A case of cannibalism in European Glass Lizard, Pseudopus apodus

Slučaj kanibalizma kod blvora, Pseudopus apodus

Preying on conspecific may be more than obtaining one more meal. There are different explanations for this behaviour, and, additionally, cannibalism may have negative effects (Pough et al., 2001). Cannibalism is documented for other reptile species (Engeman et al., 1996, Çiçek et al., 2011 Lisičić et al. 2011), but it is not reported for Pseudopus apodus. Normal diet of this lizard consists of different invertebrates and occasionally vertebrates (Arnold & Ovenden, 2002). In this short report we present cannibalistic behaviour observed in P. apodus. During field work in vicinity of Split, Croatia, on May 22th, 2011 we found adult female of P. apodus laying in the meadow, partially hidden between 30 cm tall grass, 2 m from nearest bush, with conspecific juvenile protruding from its mouth (43°32′N; 16°31′E). It was 18:45 PM, clouded, with no wind. We measured animals and habitat characteristics before realising female to nearby bush (Table 1).
