On the Temperature Corresponding to $\alpha = 0.632$

in Non-isothermal JMA Kinetics

Aleksandar Bezjak, Stanislav Kurajica, and Juraj Šipušić*

Faculty of Chemical Engineering and Technology, University of Zagreb, Marulićev trg 20, HR-10 000 Zagreb, Croatia

RECEIVED NOVEMBER 15, 2005; REVISED JUNE 7, 2006; ACCEPTED JUNE 20, 2006

The expression for rate, $da/dT$, of the nucleation and growth (NG) process under non-isothermal conditions, as described by the Johnson-Mehl-Avrami (JMA) kinetic model, served as the basis for a detailed study of a class of functions $F(m) = (da/dT)T^m$, where $m \in \mathbb{N}$. Studies of the fractional conversion, $\alpha$, of the NG process at the temperature of the maximum of function $F(m)$, $T=T(m)$, have shown that when reduced activation energy, $x = E/RT$, approaches infinity ($x \to \infty$), fractional conversion, $\alpha$, at the temperature corresponding to the maximum of function $F(m)$, $\alpha(m)$, converges to $\alpha = 0.632$, for any value of $m$. It has been further shown that fractional conversion, $\alpha$, for the NG process is equal to $\alpha = 0.632$ at the temperature corresponding to the maximum of function $F(m) = (da/dT)T^m$ for the particular value of parameter $m$ from the interval: $1 \leq m \leq 2$.

JMA
non-isothermal kinetic model

INTRODUCTION

The well known work of Criado and Ortega, Gao, Chen and Dollimore, and Malek has shown that fractional conversion, $\alpha_p$, of the non-isothermal NG process described by the JMA kinetic model, at the temperature of the maximum rate of the NG process, $T_p$, is less than 0.632. However, the exact temperature corresponding to the fractional conversion, $\alpha = 0.632$, has not been established yet.

In order to improve kinetic analysis, the product of functions has been applied, for example Malek's function $z(\alpha) = (da/dT)T^2$. This function can be considered as a special case of the functions with the general form $\Phi(m) = (da/dT)T^m$ when $m = 2$. The concept of function $\Phi(m)$ is somewhat analogous to the assisting function $\varphi$ introduced previously in the analysis of isothermal kinetic processes.

$$\Phi = F\varphi$$

The relationship between function $\Phi(m)$ and JMA function is illustrated in Figure 1. If the function $\Phi = \Phi(m) = (da/dT)T^m$ has the maximum for a selected value of $m$ at temperature $T(m)$, then at the same temperature the JMA kinetic model function has the degree of conversion $\alpha(m)$. For $m = 0$, it follows that $T(m=0) = T_p$, and function $\Phi(m=0)$ is identical with the JMA curve. Also, for this special case $\alpha(m=0) = \alpha_p$. In all other cases, i.e., for $m\neq0$, the temperature of the maximum of curve $\Phi(m)$ is different from the temperature of the maximum of the JMA curve ($T(m\neq0) \neq T_p$). Therefore, fractional conversion of the JMA process at that temperature is different from $\alpha_p$, i.e., $(\alpha(m\neq0) \neq \alpha_p)$, and corresponds to the temperature of the maximum of $\Phi$-function only, while $T(m)$ and $\alpha(m)$ are parameters of the JMA function.

In this article, the analysis of the class of functions of the general form: \( \Phi(m) = (dx/dT)T^m \) (where the value of parameter \( m \) is chosen at will) has shown that the temperature corresponding to the fractional conversion \( \alpha = 0.632 \) corresponds to the maximum of function \( \Phi(m) \), where the particular value of \( m \) lies in the interval: \( 1 \leq m \leq 2 \).

**THEORETICAL**

The reaction rate of a solid-state process is usually described by the following differential equation based on the isokinetic hypothesis and Arrhenius temperature dependency:

\[
\frac{da}{dt} = Af(\alpha) \exp \left( \frac{-E}{RT} \right) \tag{2}
\]

where \( \alpha \) is the fractional conversion at time \( t \) and \( f(\alpha) \) is an arbitrary kinetic model equation (e.g., \( n(1-\alpha)(-\ln(1-\alpha))^{1/n} \)). \( A \) is the pre-exponential factor, \( E \) is the activation energy for crystallization, \( R \) is the gas constant and \( T \) is absolute temperature.

Assuming a constant heating rate, \( \beta \), that is \( T = T_i + \beta t \) and \( dT = \beta dt \), \( g(\alpha) \) (integral form of kinetic equation) is calculated by integration of Eq. (2):

\[
g(\alpha) = \int_0^\alpha f(\alpha) \frac{Z}{\beta} \exp \left( \frac{-E}{RT} \right) dT \equiv \frac{Z}{\beta} I_A \tag{3}
\]

The integral:

\[
I_A = \int_{T_i}^T \exp \left( \frac{-E}{RT} \right) dT \tag{4}
\]

is called the Arrhenius integral. \( Z \) is the pre-exponential factor, and in this work it has been assumed to be temperature independent.

By substituting \( x = E/RT \) (reduced activation energy), Eq. (4) yields:

\[
I_A = \frac{E}{R} \int_x^\infty \exp(-x) \frac{1}{x^2} dx \tag{5}
\]

It is well known that the Arrhenius integral \( I_A \) cannot be calculated exactly and is therefore expressed by an approximate function; the most common approximation is Eq. (6):

\[
I_A = \frac{E}{R} \frac{\pi(x)}{x} \exp(-x) \tag{6}
\]

where \( \pi(x) \) denotes the function related to the integral in Eq. (5). With Eq. (6), the integral form of kinetic equation (3) reads:

\[
g(\alpha) = \frac{ZE}{\beta R} \frac{\pi(x)}{x} \exp(-x) = \exp \left\{ -x + \ln \left( \frac{\pi(x)}{x} \right) + \ln \left( \frac{ZE}{\beta R} \right) \right\} \tag{7}
\]

If the nucleation and growth process (NG) could be described by the JMA equation, \( g(\alpha) = (-\ln(1-\alpha))^{1/n} \), for the rate of NG process, one can write:

\[
\frac{da}{dT} = \frac{dI}{dT} \exp(-I) \tag{8}
\]

where:

\[
I = \exp \left\{ -nx + n \ln \left( \frac{\pi(x)}{x} \right) + n \ln \left( \frac{ZE}{\beta R} \right) \right\} \tag{9}
\]

Since:

\[
\frac{dI}{dT} = \frac{nE}{RT^2} + \frac{n}{RT} \left[ \ln \left( \frac{\pi(x)}{x} \right) \right] I \tag{10}
\]

\[
\frac{dI}{dT} = \frac{nE}{RT^2} \left( \frac{\pi'(x)}{\pi(x)} - \frac{\pi(x)}{x^2} \right) E \frac{RT}{x^2} I \tag{11}
\]

\[
\frac{dI}{dT} = \frac{nE}{RT^2} (1 + \mu(x)) I \tag{12}
\]

where:

\[
\mu(x) = \frac{1}{x} \frac{\pi'(x)}{\pi(x)} \tag{13}
\]

it follows:

\[
\frac{d\alpha}{dT} = \frac{nE}{RT^2} (1 + \mu(x)) I \tag{14}
\]

There are a number of methods for determination of the \( \pi(x) \) values. In some of them asymptotic series and complex approximations for \( \pi(x) \) are used.\(^{11-14}\) Flynn\(^{15}\) criticized some of the approximations, as he considers complex approximation\(^{16}\) to be far better. There are first to fourth degree rational approximations for the Arrhenius integral. The first degree rational approximation is the Gorbachev\(^{17}\) function with \( \pi(x) = 1/(x+2) \), and the fourth degree rational approximation is by Senum and Yang\(^{16}\) with an accuracy better than \( 10^{-5} \% \) for \( x \geq 20 \).\(^{18,19}\)

\[
\pi(x) = \frac{x^3 + 16x^2 + 86x + 96}{x^4 + 20x^3 + 120x^2 + 240x + 120} \tag{15}
\]
For small values \(^{15,16}\) of \(x\), the Arrhenius integral may be better expressed by using the power series expansion:

\[
I_a = \frac{E}{R} \left( \frac{\exp(-x)}{x} + \gamma + \ln x + \sum_{n=1}^{\infty} \frac{(-1)^n x^n}{mn!} \right) \tag{16}
\]

By coupling Eqs. (6) and (16), \(\pi(x)\) can be defined as:

\[
\pi(x) = 1 + \left( \gamma + \ln x + \sum_{n=1}^{\infty} \frac{(-1)^n x^n}{mn!} \right) x \exp(x) \tag{17}
\]

where \(\gamma = 0.5772156649\) (Euler-Mascheroni constant). The desired accuracy can be achieved by truncating the number of terms in the series.

Equations (15) and (17) can be used to calculate values for \(\pi(x)\) over the whole range of \(x\) (Table I). Table I gives the values of \(\pi(x)\), calculated at five decimals. Calculated values are checked against the tabulated values of Gautschi and Cahill\(^2\) and a very good match has been found.

As known, Doyle’s approximation presumes the same activation energy correction for a wide range of \(x\) values.\(^{21}\) For \(28 < x < 50\) the correction factor is equal to 1.052, whereas for \(18 < x < 35\) the correction factor is equal\(^15\) to 1.075. However, Doyle also carried out a function changing the correction factors continuously, resulting in \(E/(x\pi(x))\) instead of \(E^x\text{const.}\).\(^{21}\) In this work, a new expression for continuous correction has been obtained in deriving \(d/dT\) and it reads: \(E^x/(1 + \mu(x))\) (Eq. 12). The two mentioned expressions for continuous correction are in full agreement, which is confirmed by equation (1 + \(\mu(x)\)) = \(1/(x\pi(x))\) (Eq. A4).

### Application of Function \(\Phi(m)\) to the Differential Form of the JMA Kinetic Model

If \(\Phi(m)\)-function is expressed as:

\[
\Phi(m) = \frac{d\alpha}{dT} f^m = \frac{nE}{R} (1 + \mu(x)) f \exp(-J)f^m-2 \tag{18}
\]

then for \(d\Phi/dT = 0\) one obtains (Eq. A6–A9):

\[
nx(1+\mu(x))(-\ln(1-\alpha(m))-1) = m-\pi\mu(x) \tag{19}
\]

Equation (19) can be rearranged in (Eq. A4):

\[
n(-\ln(1-\alpha(m))-1) = [m-\pi\mu(x)]\pi(x) \tag{20}
\]

In some early works, it was accepted that at the maximum of the JMA curve \(\alpha_p = 0.632\). Criado and Ortega,\(^1\) Gao, Chen and Dollimore,\(^2\) and Malek\(^3,5\) rejected this wrong assumption. They have shown that fractional conversion at the maximum of the JMA curve is always smaller than 0.632, even for large values of \(x\) (as illustrated by \(\alpha_p\) values in Table II).

In this work, the analysis of \(\alpha\) values has been extended beyond the maximum of the JMA curve in order to find out the position of \(\alpha = 0.632\) for cases other than \(x \to \infty\). From the above cited works it is obvious that \(\alpha\) is equal to 0.632 at temperatures higher than that corresponding to the maximum of the experimental JMA curve, but the position of \(\alpha = 0.632\) has not been established.

</tbody>
</table>

\(\pi(x)\) values for \(x < 9\) are calculated according to Eq. (17) using 40 members of infinite row expansion. \(\pi(x)\) for \(x \geq 9\) are calculated according to Eq. (15).
From Eq. (20), it follows that:

\[
\pi(x)(m - x \mu(x)) = 0
\]  

(21)

if

\[-\ln(1 - \alpha(m)) - 1 = 0\]

(22)

i.e., \(\alpha = 0.632\). Equation (21) is satisfied when \(\pi(x) \to 0\) or/and \([m - x \mu(x)] \to 0\).

If \(x \to \infty\), then \(\pi(x) \to 0\) (Table I) regardless of the values of \(m\). It means that as \(x \to \infty\) all functions \((d\alpha/dT)T^m\) have \(\alpha(m) = 0.632\) regardless of the values of \(m\) (Figure 2a). From Figure 2a, it can be seen that as reduced activation energy, \(x\), increases, the value of the product \(\pi(x)[m - x \mu(x)]\) approaches zero and consequently fractional conversion at the maximum, \(\alpha\), approaches 0.632 (Figure 2a).

It follows from Eqs. (20)–(22) that 0.632 is the characteristic value of \(\alpha\) for the JMA kinetic model and, also, that this value does not depend on \(n\), while all the other fractional conversions depend on \(n\). The mentioned equations comprise the core of the present work. They show that \(\alpha = 0.632\) for all the \(m\)-values for which \([m - x \mu(x)] = 0\). Since it is unlikely that the \(x\)-value (and thus \(x \mu(x)\)) is known in advance, only a span can be determined within which the \(m\)-value lies. It is essential that Eqs. (20)–(22) comprise the dependence of \(m\)-values on \(x\)-values. This dependence refines Malek’s conclusion according to which \(\alpha = 0.632\) occurs at the maximum of \(x(x) = (d\alpha/dT)T^2\) function.

Precisely, if \(m < 1\) the \(\alpha\)-values increase and if \(m \geq 2\) the \(\alpha\)-values decrease towards \(\alpha = 0.632\) with an increase of reduced activation energy (Table II and Figure 2a). This fact was previously established only for \(m = 2\) (Malek’s \(z\) function).

Situations \(x \to 0\) or \(x \to 8\) are not realistic. Those are limiting cases and it is better to consider the situations for \(\approx\) small values of \(x\) or \(\approx\) large values of \(x\). In this case (\(0 < x < 8\)) \(0 < \pi(x) < 1\), and only the equation \(m - x \mu(x) = 0\) is decisive for \(\alpha = 0.632\). From Eqs. (21)–(22) it follows that for every value of \(x\) there is a value

\[m = M = x \mu(x)\]

(23)

This is illustrated in Figure 2b for three different values of \(M\). As shown in Figure 2b, the curves within the range \(1 \leq m \leq 2\) intercept the abscissa for finite \(x\), i.e. \(m = M = x \mu(x)\).

Fractional conversion \(\alpha = 0.632\) occurs at the temperature of the maximum of function \(\Phi(m)\) where the value of \(m\) is given by Eq. (23). It means that \(\alpha = 0.632\) is obtained for \(T(m=M)\). Since the possible values of the product \(x \mu(x)\) are

\[1 \leq x \mu(x) \leq 2\]

(24)

If the limit of \(x\) approaches zero, the value of \(x \mu(x)\) approaches 1, and if the limit of \(x\) approaches infinity, the value of \(x \mu(x)\) approaches 2 (Table I). It follows:

\[T(m=1) \leq T(m=M) \leq T(m=2)\]

(25)

and

\[\alpha(m=1) \leq \alpha(m=M) \leq \alpha(m=2)\]

(26)
As shown in Figure 3, the value of M is between 1 and 2. The F(M) function has the maximum at temperature T(M), where the JMA function has fractional conversion equal to α = 0.632 (hatched). Therefore, the temperature corresponding to α = 0.632 could be obtained by determining the maximum of (da/dT)*T^M function, where M = xμ(x).

**TESTING AND DISCUSSION**

To test the derived equations, 7 basic functions in the span from x₀ = 2 to x₀ = 200 have been formed. For every function T₀ = 1100 K has been taken, which according to Eq. (9) gives T = 1. Activation energy has been determined from E = x₀RT₀. In this way, the basic parameters are defined, which enables simulation of 7 different JMA curves. Characteristic values for these 7 functions are listed in Table II (x₀, E, T₀ and a₀). In addition, all relevant data for model systems, i.e., (da/dT), (da/dT)T and (da/dT)T², are given. These systems, besides x₀ = E/(RT₀) and T₀ = 1100 K, include also a constant member (as follows from Eq. 9):

\[ n \ln \left( \frac{ZE}{\beta R} \right) = \frac{nE}{RT₀} - n \ln \left( \frac{\pi(x₀)}{x₀} \right) \]  

and n = 2. All T_p and T(M) values in Table II are determined as follows: T_p values are temperatures of the maximum of simulated curves on the basis of JMA functions (da/dT)(m=0). T-values for m = 1 and m = 2 are obtained by determination of the maximum of curves (da/dT)T and (da/dT)T². All the α-values (Table II) are calculated from Eq. (28):

**Figure 2.** a) Graphical illustration of Eq. (20). It is shown that as x→x_0, [m-xμ(x)]/x→0, and therefore, α→0.632. b) Only for values of parameter m: 1 ≤ m ≤ 2 curves intercept the abscissa. Namely, for M = 1.762, M = 1.853 and M = 1.963 the curves intercept the abscissa at x = 5, 10 and 50, respectively (Table I).

**Figure 3.** Details of normalized F-functions for m = 0, 1 and 2.

</tr>
</tbody>
</table>

\[
\alpha(m) = 1 - \exp \left\{ - \frac{[m-x\mu(x)]\pi(x)}{n} - 1 \right\} \tag{28}
\]

where the corresponding value of \( x \) is calculated from: \( x = x_0T_0 / T(m) \).

It follows from the theoretical part that the determination of temperature corresponding to \( \alpha = 0.632 \) has been reduced to the determination of the maximum of the \( (\frac{dx}{dT})^zT^M \) function.

The class of functions of the general form: \( \Phi(m) = (\frac{dx}{dT})^zT^m \), where \( \alpha \) is fractional conversion of the non-isothermal process described by the JMA kinetic model and \( m \) parameter with a value chosen at will, was analyzed concerning the position of the function maximum taking into consideration reduced activation energy, \( x \).

It has been shown that as \( x \to \infty \) all functions \( (\frac{dx}{dT})T^m \) have maxima at \( \alpha(m) \to 0.632 \) regardless of the values of \( m \). With an increase of reduced activation energy \( \alpha \)-values increase towards 0.632 for \( m \leq 1 \), and decrease towards 0.632 for \( m \geq 2 \).

\[
\frac{C}{T(m=1)} + \frac{1-C}{T(m=2)} = \frac{1}{T(m=M)} \tag{29}
\]

where \( C \) is constant. In this manner, the approximation of \( x \) could be obtained. Further calculation could be performed through \( T(m=M) \approx T_0 + \Delta T \), where:

\[
\Delta T = \frac{\pi_p T_p}{n} \left\{ \exp \left[ \frac{1-\pi_p x_p}{n} \right] - 1 \right\} \tag{30}
\]

Table III give values for \( T(M) \) according to Eq. (29) with \( C = 0.3 \) and Eq. (30), as well as the best values obtained as the maximum of the expression:

\[
\Phi(M) = \left( \frac{dx}{dT} \right)^zT^m \tag{31}
\]

which always gives \( T(M) = T_0 \) (Eq. 31).

Each simulated curve has \( M \) for which function \( \Phi(M) = (\frac{dx}{dT})T^m \) has the maximum at \( T(M) \) where for the simulated curve \( \alpha = 0.632 \) (Table III). \( \alpha(M) \) is between \( \alpha(m=1) \) and \( \alpha(m=2) \), and \( T(M) \) between \( T(m=1) \) and \( T(m=2) \). All the functions \( (\frac{dx}{dT})T^m \) for \( M < m \leq 2 \) have maxima at \( T = T(m) \), for which \( \alpha \) of the JMA curve is greater than 0.632. All the functions \( (\frac{dx}{dT})T^m \) for \( 1 \leq m < M \) have maxima at \( T = T(m) \) for which \( \alpha \) of JMA curve is less than 0.632.

These facts give a new insight into the position of \( \alpha = 0.632 \), as shown in Table IV, where previous findings concerning this problem are chronologically listed.

The results outlined in the last row of Table IV, are based on Eq. (21).

CONCLUSIONS

The exact temperature \( T(M) \) corresponding to the fractional conversion \( \alpha(M) = 0.632 \) can be determined only if the value of the reduced activation energy, \( x \), is known.

At the current state of measurement techniques, these findings are of little help in the determination of kinetic parameters but offer a contribution to a better understanding of the properties of the JMA kinetic model in non-isothermal conditions.
APPENDIX

Going from Eq. (17) which reads:

\[ p(x) = 1 + \left( \gamma + \ln x + \sum_{n=1}^{\infty} \frac{(-1)^n x^n}{n!} \right) \exp(x) \]  

(A1)

and its derivative, by taking into account:

\[ \sum_{n=1}^{\infty} \frac{(-1)^n x^n}{n!} = \exp(-x) - 1 \]

one obtains:

\[ \frac{d\pi}{dx} = \pi'(x) = \frac{(1 + x)\pi(x) - 1}{x} \]  

(A2)

i.e.,

\[ \frac{\pi'(x)}{\pi(x)} = 1 + \frac{1}{x} - \frac{1}{x\pi(x)} \]  

(A3)

From Eq. (13), it follows:

\[ x\pi(x)(1 + \mu(x)) = 1 \]  

(A4)

\[ \frac{d\alpha}{dT} \frac{1}{\beta} = \frac{d\alpha}{dT} = \frac{d\alpha}{dT} \frac{d\ln(1 + x\mu(x))}{dT} \exp(-J) = \frac{nE}{RT^2} (1 + x\mu(x)) \exp(-J) \]  

(A5)

and

\[ \Phi(m) = \frac{d\alpha}{dT} \frac{1}{T^m} = \frac{nE}{R} (1 + x\mu(x)) \exp(-J) \frac{1}{T^{m-2}} \]  

(A6)

for \( d\Phi/dT = 0 \):

\[ \frac{nE}{R} I \exp(-J) \frac{1}{T^{m-2}} \]

\[ \left[ \frac{d\mu(x)}{dT} T^2 + \frac{nE}{R} (1 + x\mu(x))(1 - I) + (1 + x\mu(x))(m - 2)T \right] = 0 \]  

(A7)

\[ \frac{d\mu(x)}{dT} T^2 = \frac{d\mu(x)}{dT} E \frac{1}{R} = -\frac{d(1/x\pi(x))}{dx} \frac{E}{R} \]

SAŽETAK

Položaj $\alpha = 0,632$ u neizotermnoj JMA kinetici

Aleksandar Bezjak, Stanislav Kurajica i Juraj Šipušić

Johnson-Mehl-Avramijev matematički model brzine procesa nukleacije i rasta, $da/dT$, u neizotermnim uvjetima uporabljen je kao osnova za proučavanje funkcija oblika $\Phi(m) = (da/dT)T^m$, gdje je $m \in \mathbb{R}$. Proučavanjem konverzije, $\alpha$, procesa nukleacije i rasta pri temperaturi maksimuma funkcije $\Phi(m)$, $T = T(m)$, pokazano je da kada reducirana energija aktivacije, $x = E/RT$, teži u beskonačnost ($x \rightarrow \infty$), konverzija pri temperaturi koja odgovara maksimumu funkcije $\Phi(m)$, $\alpha(m)$, teži vrijednosti 0,632 za svaki $m$. Nadalje, pokazano je da, bez obzira na iznos reducirane energije aktivacije, konverzija procesa nukleacije i rasta iznosi 0,632 pri temperaturi maksimuma funkcije $\Phi(m)$ za određenu vrijednost parametra $m$ iz intervala: $1 \leq m \leq 2$.
