Pandža, M. & Milović, M.: Flora of the islets near Pakoštane (Dalmatia, Croatia). Nat. Croat., Vol. 24, No. 1, 19–35, 2015, Zagreb.

During 2004 and 2012 field research into the flora of the five uninhabited islets near Pakoštane, Dalmatia, South Croatia was carried out: Babuljaš, Veliki Školj, St Justina, Mali and Veliki Žavinac. Altogether, 257 vascular flora taxa were recorded. The flora of the islet Veliki Školj had 159 taxa, that of St Justina 118, Veliki Žavinac 115, Mali Žavinac 105 and Babuljaš 95.

The largest number of taxa were found in the families *Fabaceae* (40 taxa; 15.56%), *Poaceae* (36 taxa; 14.00%) and *Asteraceae* s.l. (31 taxa; 12.06%). Regarding life forms, therophytes prevailed (49.42%). The chorological spectrum highlights a clear dominance of Mediterranean taxa (50.19%). Their percentage contribution did not significantly differ among the islets (47.62–53.04%).

There were four endemic, eight endangered and eight strictly protected plant taxa. No neophytes were found except *Conyza sumatrensis* which was observed on the islet of St Justina.

Key words: diversity, vascular flora, small islets, Adriatic Sea, Dalmatia, Croatia

Pandža, M. & Milović, M.: Flora otočića ispred Pakoštana (Dalmacija, Hrvatska). Nat. Croat., Vol. 24, No. 1, 19–35, 2015, Zagreb.

Tijekom 2004. i 2012. provedena su terenska istraživanja flore na pet nenaseljenih otočića ispred Pakoštana: Babuljaš, Veliki Školj, Sveta Justina, Mali i Veliki Žavinac. Utvrđeno je ukupno 257 svojti vaskularne flore. Flora Velikog Školja ima 159 svojti, Sv. Justine 118, Velikog Žavinca 115, Malog Žavina 105 i Babuljaša 95 svojti.

Porodice s najvećim brojem svojti su *Fabaceae* (40 svojti; 15,56 %), *Poaceae* (36 svojti; 14,00%) i *Asteraceae* s.l. (31 svojta; 12,06%). Terofiti su najzastupljeniji životni oblik (49,42%), a među flornim elementima najzastupljenije su mediteranske biljke (50,19%). Biljke mediteranskog rasprostranjenja približno su jednako (47,62–53,04%) zastupljene na svim otočićima. Zabilježena su četiri endema, osam ugroženih te osam strogo zaštićenih biljaka. Od neofita, na Sv. Justini je zabilježena samo vrsta *Conyza sumatrensis* dok na ostalim otočićima neofita nije bilo.

Ključne riječi: raznolikost, vaskularna flora, otočići, Jadransko more, Dalmacija, Hrvatska

INTRODUCTION

According to DUPLANČIĆ LEDER *et al.* (2004) in the Croatian part of the Adriatic Sea there are 79 islands (area $>1 \text{ km}^2$), 525 islets ($0,01 - 1 \text{ km}^2$) and 642 rocks and rocks awash ($< 0,01 \text{ km}^2$). In general, the larger and inhabited islands of the Adriatic archipelago are botanically well explored and recognized as one of the major centers of plant diversity in Croatia (NIKOLIĆ *et al.*, 2008, 2014). But there is still a significant number of uninhabited

ted islets and reefs where the vascular flora, apart from a few exceptions (HEĆIMOVIC, 1982; PANDŽA, 2002; PAVLETIĆ, 1983; JASPRICA & RUŠČIĆ, 2013; SKELIN *et al.*, 2014), is practically unexplored. There are five islets off the village of Pakoštane (Zadar archipelago, north Dalmatia): Babuljaš, Veliki Školj, St Justina, Mali Žavinac and Veliki Žavinac (Fig. 1) whose flora has never been investigated before. The aim of this study is to investigate the vascular flora of these five islets and to compare it with other small uninhabited islets of the Adriatic archipelago.

STUDY AREA

The islets which are the subject of this study are part of the Zadar archipelago, which belongs to the group of North Dalmatian islands (STRĀŽIĆIĆ, 1987), Fig. 1. They are situated off the village of Pakoštane at distances from 260 m (St Justina) to 570 m (Veli Skoj) from the nearest shore (Fig. 1). Four of them are considerably smaller than 1 km² which puts them into the islets category: Veliki Školj (0.0549 km²), St Justina (0.0125 km²), Žavinac Mali (0.0115 km²) and Žavinac Veliki (0.0277 km²). Babuljaš (0.0078 km²) is included

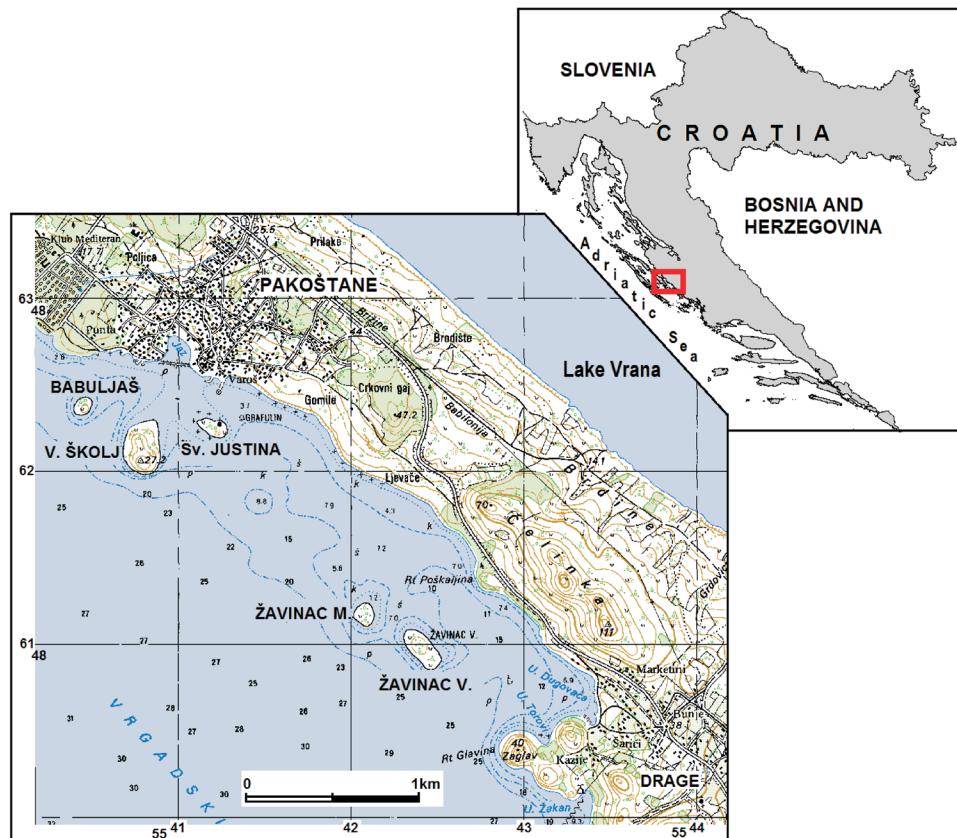

Fig. 1. Geographical position of the studied islets.

into the reefs category (DUPLANČIĆ LEDER *et al.*, 2004). All of them are uninhabited and are included into the group of small, occasionally inhabited or uninhabited islands and islets – MPNNOo, the Area of Special State Concern (ANONYMOUS, 2007). *The National Programme for Protection and use of MPNNOo* was adopted in order to protect them from inappropriate and unplanned management.

Although they are located very close to the mainland, there is little human impact on the investigated islands. On St Justina people occasionally pay visits to the small church and tend the small olive grove that has been recently planted and the islet of Veliki Školj is used for goat grazing.

According to Köppen classification, they are within the C_{sa} climate zone (BERTOVIĆ, 1975; ŠEGOTA & FILIPČIĆ, 2003) characterized by hot summers with the average monthly temperature of $\geq 22^{\circ}\text{C}$. The nearest weather station in Biograd reported the average annual precipitation of 815.4 mm and the average annual air temperature was 15°C for the period from 1981–2010. The lowest precipitation values were recorded in July, 23.5 mm average and the highest in the period from October to March. These are typical maritime precipitation regime characteristics (PENZAR & PENZAR, 1979/80; 1981). During summer, vegetation practically stops growing due to harsh droughts.

These islets are situated within the Eu-Mediterranean belt of evergreen vegetation of the *Fraxino ornis-Quercion ilicis* Biondi, Casavecchia & Gigante 2013 alliance while the coastal area belongs to the *Plantagini-Limonietum cancellati* Horvatić (1934) 1939 association. The muddy soil in the north-west of the St. Justina islet is covered by the *Puccinellio festuciformis-Salicornietum fruticosae* (Br.-Bl. 1928) Géhu 1967 association (Croatian National Classification of Habitats, NCH – F.1.1.3.1 – endangered and protected habitat, TOPIĆ & VUKELIĆ, 2009) which is mentioned in Directive 92/43 EEC (ANONYMOUS, 1992). Mosaics of low bushes and clearings with dry grassland vegetation can be seen on every islet.

METHODS

Field work on flora inventory was performed in 2004 and 2012. Identification of plant taxa was carried out using the standard floristic literature: BONNIER (1911–1935), FIORI (1923–1929), HAYEK (1924–1933), HEGI (1936–1987), TUTIN *et al.* (1968–1980, 1993), HORVATIĆ & TRINAJSTIĆ (1967–1981), TRINAJSTIĆ (1975–1986), JAVORKA & CSAPODY (1975), PIGNATTI (1982) and DOMAC (1994). The nomenclature of plant taxa follows NIKOLIĆ (2014a).

The list of families, genera, species and subspecies is given in alphabetical order and is organised within higher system units. Designations for islets, life forms, chorological type (geoelement), threatened and protected status were provided for taxa in the flora list.

Based on the life form classification of RAUNKIAER (1934), biological form was verified in the field and denoted according to categories reported in HORVAT (1949) and PIGNATTI (1982): **T** – *Therophytes*, **G** – *Geophytes*, **H** – *Hemicryptophytes*, **Ch** – *Chamaephytes* and **P** – *Phanerophytes*.

The division of the plants into floral elements and lower categories was made according to HORVATIĆ (1963) and HORVATIĆ *et al.* (1967–1968). In the list of flora, each species name is followed by the floral element and marked as follows:

1. MEDITERRANEAN (MED)

- 1.1. Circum-Mediterranean (CM)
- 1.2. West Mediterranean (ZM)
- 1.3. East Mediterranean (IM)
- 1.4. Illyrian Mediterranean plants
 - A) Illyrian South European (ILJEU)
 - B) Illyrian Adriatic plants
 - a) Illyrian Adriatic Endemic plants (ILJAE)
 - b) Illyrian Apennine plants (ILAP)
- 1.5. Mediterranean Atlantic (MA)
- 1.6. European Mediterranean (EUM)
- 1.7. Mediterranean Pontic (MP)

2. SOUTH EUROPEAN (SEU)

- 2.1. South European Mediterannean plants (JEUM)
- 2.2. South European Pontic (JEUP)
- 2.3. South European-Atlantic (JT)

3. ATLANTIC PLANTS (AN)

4. EAST EUROPEAN-PONTIC (IEP)

5. EUROPEAN (EF)

6. EUROASIATIC (EAF)

7. CIRCUM-HOLARCTIC (CIRC)

8. WIDESPREAD PLANTS (ŠR)

9. CULTURAL AND ADVENTIVE PLANTS (N)

In the list of flora the islets are marked by numbers given after the floral element: 1 – Babuljaš, 2 – Veliki Školj, 3 – St. Justina, 4 – Žavinac Mali and 5 – Žavinac Veliki. Abbreviation “end” in the list of flora stands for endemic taxa, as classified by NIKOLIĆ (2014a).

Species from the Red Book List of the Vascular Flora of Croatia (NIKOLIĆ & TOPIĆ, 2005; NIKOLIĆ 2014b) are marked by proper abbreviations showing the degree of each species endangerment: Endangered (EN), Vulnerable (VU), Near Threatened (NT), Least Concern (LC) and Data Deficient (DD).

Taxa protected by the Nature Protection Act (ANONYMOUS, 2013a) and listed in the Ordinance on Designating Wild Taxa Protected (ANONYMOUS, 2013b) are denoted as “spr”-strictly protected.

In the floristic list, habitats are given after the phytogeographical element and marked by letters as follows: a – macchia and garrigue, b – Aleppo pine forests; c – dry grasslands; d – ruderal habitats; e – muddy and salty soils; f – rocky sea shores; g – rocks and cracks in the walls; h – parasites on the plants.

ANALYSIS OF THE FLORA

Taxonomical analysis

On the five uninhabited islets situated in the vicinity of village of Pakoštane, there were 257 vascular flora taxa (225 species and 32 subspecies), which were classified into 169 genera and 54 families (Tab.1). This is the first recording of the taxa for these islets.

The largest number of taxa was found on Veliki Školj (159), followed by St. Justina (118), Žavinac Veliki (115), Žavinac Mali (105) and Babuljaš (95) (Tab. 2).

As expected, the largest number of taxa is recorded for V. Školj (159). It has the largest area (0,055 km²), the highest point above the sea level (27 m) and it is moderately exposed to anthropogenic influence (goat grazing). The other four islets are smaller (0,008 – 0,028 km²), and are lower lying, which makes their vegetation completely exposed to salinization. St. Justina (0,013 km²) is one-half the size of Žavinac Veliki (0,028 km²) but has the largest number of taxa (118 vs. 115). This is due to the greater human influence: a small olive grove has been recently planted on St Justina creating a new type of habitat and resulting in an increase in the richness of the flora.

The results indicate that the richness of the vascular flora of these five islands is influenced more by the diversity of habitats and anthropogenic elements than by the areas of islets.

Families with the highest number of taxa were: *Fabaceae* (15.56 % of the total flora), *Poaceae* (14.00 %) and *Asteraceae* s.l. (12.06 %). Their contribution to the total number of taxa was 42% of the total flora (Tab. 3). These families are also predominant on other Dalmatian islands and islets: Lokrum, Bobara and Mrkan (Hećimović, 1982), Žirje (Pandža, 2003), Ist and Škarda (Milović & Pandža, 2010), Obonjan (Milović, 2004a), Supetar (Jasprica & Ruščić, 2013) etc.

Analysis of the life forms

As expected, the proportion of therophytes in the flora of the investigated islets was high (49.42%) (Fig. 2). This was also shown for each particular islet (Tab. 4).

The proportion of therophytes ranges from 41.53 % on St. Justina to as much as 61.04% on Babuljaš. Therophytes are also the predominant life form in other Dalmatian islets'

Phytogeographical analysis

As the region of this research belongs to the typical Mediterranean climate, the phytogeographical analysis results (Tab. 6) were as expected: plants of the Mediterranean floral element are the most common (50.19 %). They are followed by widespread (20.23%) and South European plants (17.90%). Such a predominance of Mediterranean plants was also recorded in some other Dalmatian islands' flora (e.g. MILOVIĆ, 2004a, PANDŽA *et al.*, 2011).

Although they are situated only a small distance (less than 0.6 km) from the mainland (Fig. 1), anthropogenic influence on the investigated islets is insignificant, with the exception of Veli Škoj (grazing goats) and St. Justina (a small olive grove). Therefore, the poor representation of alien plants (0.78% of the total flora) was expected. Low representation of suitable anthropogenic habitats and the exposure of the islets to salinization are the main limiting factors for the immigration of adventive plants. Only two of them were found, both on islet of St. Justina. Olive trees (*Olea europaea*) have recently been brought into cultivation. The neophyte taxon *Conyza sumatrensis* has been accidentally brought. This taxon is currently spreading invasively throughout Dalmatia, south Croatia (MILOVIĆ, 2004b).

**Fig. 2.** Spectrum of life forms in the flora on the all investigated islets.

Tab. 6. Floral elements analysis of the flora of the islets near Pakoštane.

Geoelements	No. of taxa	%
MEDITERRANEAN – MED	129	50.19
SOUTH EUROPEAN – SEU	46	17.90
ATLANTIC PLANTS – AN	1	0.39
EAST EUROPEAN-PONTIC – IEP	2	0.78
EUROPEAN – EF	4	1.56
EUROASIATIC – EAF	19	7.39
CIRCUM-HOLARCTIC – CIRC	2	0.78
WIDESPREAD PLANTS – ŠR	52	20.23
CULTURAL & ADVENTIVE – N	2	0.78
TOTAL	257	100.00

In the flora of the investigated region, four endemic, eight endangered and eight strictly protected taxa were found. Three endemic taxa were found on dry rocky grasslands (*Vincetoxicum hirundinaria* ssp. *adriaticum*, *Carduus micropterus* ssp. *micropterus* and *Aurinia sinuata*) while *Limonium cancellatum* grows on rocks in the halophytic zone. There were two endangered (*Carex divisa* and *C. extensa*) and two vulnerable (*Desmazeria marina* and *Parapholis incurva*) taxa, and they are also found in the coastal zone which is exposed to salinization.

CONCLUSION

In this study, 257 plant taxa (species and subspecies) are recorded for the first time for the five uninhabited islets near Pakoštane, North Dalmatia. Due to the small surface areas and some particular ecological conditions, the flora of islets showed characteristics similar to those of some other Dalmatian islands. These results contribute to the broadening of our knowledge on the vascular plant diversity of the uninhabited Adriatic islands.

ACKNOWLEDGEMENTS

We would like to thank the two anonymous reviewers for their constructive comments on an earlier version of this manuscript.

SAŽETAK

Flora otočića ispred Pakoštana (Dalmacija, Hrvatska)

M. Pandža & M. Milović

Vaskularna flora nenaseljenih i slabo naseljenih otočića i hridi hrvatskog otočnog arhipelaga je slabo istražena. Tijekom 2004. i 2012. provedena su terenska istraživanja flore na pet nenaseljenih otočića ispred Pakoštana (zadarski arhipelag, sjeverna Dalmacija): Babuljaš, Veliki Školj, Sveta Justina, Mali i Veliki Žavinac. Zbog male površine i male nadmorske visine, vegetacija istraživanih otočića gotovo je u cijelosti izložena zaslanjivanju. Značajnjem antropogenom utjecaju izloženi su samo Sv. Justina (maslinik i crkvica) i Veliki Škoj (ispava koza). Za pet istraživanih otočića utvrđeno je ukupno 257 svojti vaskularne flore. Flora Velikog Školja ima 159 svojti, Sv. Justine 118, Velikog Žavinca 115, Malog Žavinca 105 i Babuljaša 95 svojti. Zabilježeni broj svojti ne odstupa značajno u odnosu na broj svojti koji je zabilježen za druge nenaseljene otočice u Dalmaciji.

Rezultati taksonomske, fitogeografske i ekološke analize flore su očekivani s obzirom na fitogeografski položaj i tipičnu mediteransku klimu i u skladu su s rezultatima utvrđenim za floru drugih dalmatinskih otočića. Porodice s najvećim brojem svojti su *Fabaceae* (15,56%), *Poaceae* (14,00%) i *Asteraceae* s.l. (12,06%). Terofiti su najzastupljeniji životni oblik (49,42%), a među flornim elementima najzastupljenije su mediteranske biljke (50,19%), koje su približno jednakom zastupljene u flori svih pet otočića (47,62–53,04%). U flori istraživanih otočića su značajno zastupljene svojte od posebnog interesa: zabilježena su četiri endema, osam ugroženih te osam strogo zaštićenih svojti. Od neofita, na Sv. Justini je zabilježena samo vrsta *Conyza sumatrensis* dok na ostalim otočićima neofita nije bilo. Izostanak većeg broja stranih vrsta posljedica je slabo izraženog antropogenog utjecaja i izostanka odgovarajućih staništa pogodnih za njihovo useljavanje.
