

EFFECT OF ADDITIVES ON BIG BALE SILAGE QUALITY AND  
MILK PRODUCTION

T. Heikkilä, V. Toivonen, T. Tupasela

*Introduction*

Wilting and big baling is becoming more popular in grass silage making in Finland. Farmers normally use additives on grass when harvested. However, all big bales are not treated with additives, although in many studies additive treatment has improved chemical and microbial quality of big bale silage.

The aim of this experiment was to study the effects of three prewilted big bale silages preserved with no additive, inoculant or formic acid on silage quality and silage intake, on milk yield and milk composition.

*Materials and methods*

Big bale silages were made from the first-cut timothy-meadow fescue sward after wilting of 8 h. Bales were wrapped with six layers of plastic film using 50% overlapping. Additive treatments were:

- no additive
- inoculant (*Lactobacillus rhamnosus* + *Propionibacterium shermanii*,  $5 \times 10^6$  cfu/g)
- acid (80 % formic acid + 2 % orthophosphoric acid, 5 l/t)

*Milk production experiment:*

- 12 Finnish Ayrshire cows in their 2.-7. lactation
- 4 x (3x3) latin square design with 4 weeks period
- silages were given *ad libitum*
- concentrate 9 kg/d (oats-barley-rape seed meal-minerals: 405 - 405 -150 - 40 g/kg).

Digestibility of feeds was determined in 3 wethers by total collection and digestibility of total diet in cows by using acid insoluble ash (AIA) as an internal marker.

Rad je priopćen na 40th EAPP, Vienna, 1997.

### Results

- Fermentation quality of all silages was good
- pH and the extent of proteolysis was higher in untreated than in inoculant or formic acid treated silages
- Lactic acid was higher and sugar content and pH lower in inoculant in untreated silage
- Aerobic stability in acid treated silage was better than in untreated or inoculant treated silages.

Feedvalues are calculated according to digestibility measured by sheep

– Digestibility of total diet was better in cows given inoculant treated silage than in cows given acid or untreated silage.

There was no difference in digestibility of silages in wethers.

Table 3. - DIGESTIBILITY OF TOTAL DIET IN COWS

| Additive                 | Digestibility -% |             |             |      |                |
|--------------------------|------------------|-------------|-------------|------|----------------|

| No vs. Additive          |                  |             |             | *    |                |
| Inoculant vs. Acid       | ***              | ***         | **          | ***  | ***            |

– Intake of acid treated silage was 3% higher than that of untreated or inoculant silages

– Milk and protein yield and protein concentration were higher, curd firmness ( $A_{10}$ ) and sensory quality of milk (smell and taste) were better in milk produced by cows given silages treated with additives compared with untreated silage

– Inoculant and acid treated silages produced same protein yield

– Milk urea was lower in cows fed with formic acid than with inoculant or untreated silages.

### Conclusion

Silage additives are recommended for wilted big bale silage to improve milk and protein yield, milk quality and economy of milk production.

### DJELOVANJE ADITIVA NA KVALITETU SILAŽE U VELIKIM BALAMA I PROIZVODNJI MLIJEKA

#### Sažetak

Ostavljanje trave da uvene i spremanje u velike bale postaju sve popularniji u proizvodnji silaže u Finskoj. Farmeri obično stavljaju aditive na travu kod košnje. Međutim, sve se velike bale ne tretiraju aditivima, iako je tretiranje aditivima prema mnogim istraživanjima poboljšalo kemijsku i mikrobsku kvalitetu silaže u velikim balama.

Cilj je ovog pokusa bio proučiti djelovanje (učinak) tri prethodno uvenule silaže u velikim balama, konzervirane bez aditiva, cjepiva ili mravlje kiseline, na kvalitetu i konzumiranje silaže, te na količinu i sastav mlijeka.
