Circularly Polarised Hexagonal Patch Antenna With Polygonal Slot for RFID Applications

Prakash K. C, Vinesh P. V, Vivek R, Mohammad Ameen, and Vasudevan K

Abstract — A compact single feed circularly polarized microstrip patch antenna for RFID applications is proposed. Antenna geometry includes a regular hexagon shaped patch with a polygonal slot embedded at the centre. The slot accounts for circular polarization and an area reduction of 22.5%. It is fabricated on FR4 substrate with dielectric constant 4.4 and size 50 mm x 50 mm x 1.6 mm. The measured results include 10dB impedance bandwidth of 5.5% at the center frequency of 2.42 GHz, a return loss of 32 dB, minimum axial ratio of 1.82 dB, axial ratio bandwidth of 7.5%, gain of 4.9 dBi with a broadside radiation characteristic for the RHCP antenna. These results are well in tune with the simulated results and the proposed design is suitable for RFID reader antenna applications.

Index terms — circularly polarized, hexagonal patch antenna, polygonal slot, RFID

I. INTRODUCTION

RFID based identification of objects and people have become highly popular. The RFID system generally consists of two basic components; the reader and the tag. The reader is a read or read/write device that uses an antenna to send a radio frequency electromagnetic field to the tag. The tag is the data carrying device located on the object being identified. RFID reader antennas widely use circularly polarized single feed microstrip patch antennas in order to overcome false identification of targeted objects [1]. Commonly used design of circularly polarized patch antennas either excite two orthogonal modes of a symmetrical patch (single coaxial feed) or patch antennas with two orthogonal feeds which are in quadrature. Various advantages of single feed circularly polarized antennas include reduced feeding circuit complexity, less weight, compact and preferred in situations where it is difficult to accommodate dual orthogonal feeds. The proposed single feed circularly polarized antenna is distinct due to several features. Perturbation methods are employed to bring circularly polarized radiation. Currently a wide variety of perturbation methods are there. The methods include, using a cross slot embedded on the radiating patch [2], truncating the corners of a square patch and inserting slits of different lengths at the edges of a square patch [3], the combination of two equal right angle antennas with two orthogonal feeds which are in quadrature.

the slot antennas with equal perpendicular length on the ground plane fed by microstrip line [4], inserting an elliptical slot at centre of a circular patch [5], a circular patch with a rectangular slot oriented at 45° [6], two asymmetric orthogonal slits positioned in the centre of the patch antenna [7]. In the proposed antenna instead of an elliptical slot, irregular hexagonal slot is cut in a hexagonal patch. In this article the promising design of a single co-axially fed circular polarized microstrip antenna is presented. The design strategy in this work is simultaneous control over frequency, axial ratio and input impedance and thereby achieving CP and matching conditions. This is achieved with the choice of shape for the central slot and the feed point. The insertion of the slot is to i) produce circularly polarized radiation in the required band ii) reduce the size of the patch and iii) bring down resonant frequency. The choice of dimensions of the central irregular slot and the feed position ensures the splitting of the fundamental mode into degenerate modes and phase quadrature between these modes. These degenerate modes should have equal amplitude and exact phase quadrature to ensure circularly polarized radiation. A circular patch antenna with central elliptical slot is used to generate CP radiation in [5]. It is substantiated in Section IV that all the measured values of the proposed antenna in this work are superior to other similar works in literature. The dimensions of the patch and slot, feed point locations are optimized for good performance. Ansoft HFSS is used for the simulation and analysis of the structure. The antenna performance is evaluated using ZVB20 vector network analyzer.

The proposed RHCP antenna has got a 10 dB impedance bandwidth of 130 MHz (2.355GHz to 2.485 GHz) and axial ratio bandwidth of 180 MHz (2.32 GHz to 2.5GHz) and a gain of 4.9dBi. Though this band is usable for WLAN and Bluetooth applications, the obtained gain, axial ratio bandwidth and 80° 3dB beam width are promising factors for its appropriateness for active RFID reader antenna applications. However this gain is insufficient for long range applications, it can be enhanced by incorporating stacking concept.

Active RFID and passive RFID technologies are basically different technologies with substantially distinct capabilities. In terms of communication range, active RFID offers a range of more than 100m, while it is nearly 12m for passive RFID systems. Active RFID collects signals from 1000s of tags by the reader while it is 100s in UHF passive RFID systems. Active RFID has got the ability to continuously monitor and record sensor input, whereas the passive RFID system has got the ability to read and transfer sensor values only when the tag is...
powered by the reader. Active RFID has got large read/write data storage (128KB) with sophisticated data search and access capabilities, whereas the passive RFID has got small read/write data storage. Active RFID is capable of area monitoring, sophisticated cargo security applications and unconstrained asset movement. When considering the cost, this is less for UHF passive RFID.

The novelty of the proposed antenna is its shape, area reduction, compactness and the mode of generation of circularly polarized radiation. The authors have experimentally proved in [8] that when the patch shape is dodecagonal gain is slightly less (4.82 dBi – 4.67 dBi), ARBW is 5.5% and when the shape is hexagonal with elliptical and circular slots the gain is 4.5 dBi and ARBW is 5.8% [9]; both designed for the same resonant frequency 2.45GHz.

The measured parameters of the antenna show its suitability for active RFID reader antenna applications.

II. ANTENNA GEOMETRY

The proposed antenna is fabricated on 50mm x 50mm FR4 substrate, with dielectric constant 4.4, thickness 1.6 mm and a tan δ=0.02. It consists of regular hexagonal patch with an irregular polygonal slot.

![Feed point for RHCP](image)

![Feed point for LHCP](image)

![Central irregular hexagonal slot geometry](image)

Fig. 1. Geometry of the proposed antenna. (a) side view (b) Top view of RHCP antenna (c) Top view of LHCP antenna. (d) central irregular hexagonal slot geometry. Guided wavelength \( \lambda_d = 0.0604 \text{ m} \), \( a = 17.244\text{ mm}(0.285 \text{ } \lambda_d) \), \( b = 1\text{ mm}(0.0166 \text{ } \lambda_d) \), \( c = 7\text{ mm}(0.116 \text{ } \lambda_d) \), \( d = 11.4\text{ mm}(0.189 \text{ } \lambda_d) \), \( k = 1.62 \), \( L = W = 50\text{ mm}(0.8278 \text{ } \lambda_d) \), X(21mm,19mm), Y(21mm,31mm).

The patch is fabricated using copper material of thickness 0.035 mm on the top side of the substrate and the copper ground plane is of dimensions 50mm x 50mm x 0.035mm on the bottom side of the substrate. As depicted in Figure 1, the irregular hexagonal slot is situated on the centre of the patch oriented along the X axis. The dimensions of the hexagonal slot are designated as i) \( b \) - the smaller Y axis dimension (top and bottom width), ii) \( c \) - the larger Y axis dimension (central width) and iii) \( d \) – the larger X axis dimension (height). These dimensions are such that \( b < c < d \). The ratio ‘\( k \)’ is defined as ratio of ‘\( d \)’ to ‘\( c \)’ with ‘\( b \)’ constant. In order to generate circularly polarized waves, the simplest approach is to excite two equal amplitude degenerate orthogonal modes by a single feed point at an estimated location. By introducing some asymmetry in the structure the resonant frequencies of two degenerate modes can be made slightly different from each other and a phase difference of 90° between the two amplitudes can be achieved [10]. The simplest way to split the fundamental TM\(_{11}\) mode is, cut a thin slit through the centre [5]. In this proposed antenna a hexagonal slot with unequal sides is chosen as the asymmetry or detuning element, in order to radiate circularly polarized waves. The radiation of circularly polarized wave is highly sensitive with respect to the position of the feed location and the dimensions of the central slot. The antenna is excited through co - axial probe at the location X to produce Right Handed Circular Polarisation (RHCP) and at the feed location Y to radiate electromagnetic waves with Left Handed Circular Polarisation (LHCP). The co-axial probe feed point for RHCP antenna is the mirror image as that for LHCP antenna with respect to the centre of the patch. The feed location is chosen along the locus of 50 \( \Omega \) characteristic impedance and is adjusted for good matching. The method of size reduction resorted to in this piece of work yields improved gain and axial ratio bandwidth compared to similar works in literature [1] to [10] and enunciated in Section IV.

III. THEORY & DESIGN

**Theory of Circularly polarized Radiation**

When a patch antenna is considered its mode impedance \( Z_{\text{mm}}(\alpha) \) may be expressed as in [5]

\[
Z_{\text{mm}}(\alpha) = R_{\text{mm}} e^{j\theta_{\text{mm}}(\alpha)}
\]  

(4)
Where $m,n = 0,1,...$, are the vertical and horizontal dimensions respectively. $R_{mn}$ represents the sum of the radiation, dielectric and metal losses, $\zeta_{mn}(\omega)$ is the normalized frequency response written in terms of the quality factor $Q_{mn}$ and modal resonance frequency $\omega_{mn}$. The quality factor $Q$ depends to a large extent on the antenna geometry. By the proper selection of the feed point, the dominant mode is detuned into two equal amplitude orthogonal degenerate modes. Consider the antenna geometry where a single mode is detuned into two orthogonal modes $TM_e$ and $TM_o$ neglecting the effects of higher order modes. Here $TM_e$ is the orthogonal even mode and $TM_o$ is the orthogonal odd mode. Even mode is the mode that is symmetric with respect to the ‘Y’ axis and odd mode is with respect to the ‘X’ axis. Correspondingly total input impedance may be written as [5]

$$Z_{in} = Z_e + Z_o$$  \hspace{1cm} (5)

Where $Z_e$ and $Z_o$ are the corresponding even mode and odd mode impedances, $\omega_e$ and $\omega_o$ are the corresponding modal frequencies, with $\omega_e < \omega_o$. By introducing the asymmetry due to the irregular polygonal slot, the resonant frequencies of two degenerate modes are made slightly different from each other and a phase difference of 90° between the two amplitudes is achieved. The normalized impedance ratio of odd to even mode is defined as in [5]

$$\beta(\omega) = \frac{\zeta_e(\omega)}{\zeta_o(\omega)} = \frac{1+jQ}{1+jQ(\frac{\omega_o}{\omega_e} - \frac{\omega_e}{\omega_o})}$$  \hspace{1cm} (6)

The angle of $\beta(\omega)$ is the phase difference of the CP field components, while the magnitude is proportional to the axial ratio. Here the angle of $\beta(\omega)$ is designed to be obtained as 90° and the magnitude to be less than 3dB. The slot is introduced at the centre. As the fundamental mode exhibits a zero in the central area the fields will not be affected significantly. The fundamental mode splits into degenerate orthogonal modes by the proper choice of feed point and asymmetry. For the odd mode, which is oriented towards the slot (X axis), the perturbation is minimum as the top and bottom width of the slot is made narrow enough. If the slot had been a rectangular perturbation is minimum as the top and bottom width of the slot is nearly equal amplitude and with a phase difference of 90° for the degenerate modes [12].

**Design**

The design equations of the hexagonal patch antenna are derived in a similar approach as that of a circular patch. As the two shapes are equivalent to each other the equations for resonant frequency, effective radius of the circular patch are adopted as such[10]. The side length ‘a’ of the regular hexagon for a resonant frequency of $f_e = 2.687\,\text{GHz}$ is designed as follows. The dominant mode resonance frequency of a circular patch is given by [11]

$$f_e = \frac{X_{mn}\varepsilon}{2\pi r_e\varepsilon_r}$$  \hspace{1cm} (1)

where $f_e$ is the resonant frequency of the patch, $X_{mn} = 1.8411$ for the dominant mode $TM_{11}$, $\varepsilon$ is the velocity of light in free space, $\varepsilon_r$ the relative permittivity of the substrate, ‘$r_e$’ is the effective radius of the equivalent circular patch and is given by [11]

$$r_e = r \left[1 - \frac{2h}{m\pi r}(\ln \frac{\pi r}{2h} + 1.7726)\right]^{0.5}$$  \hspace{1cm} (2)

where ‘r’ is the actual radius of the circular patch and ‘h’ is the height of the substrate. Then by equating the areas of a circle and a regular hexagon, the edge or side length of the regular hexagon ‘a’ may be found out as [11],

$$a = 1.099 \, r_e$$  \hspace{1cm} (3)

By selecting proper slot dimensions and by choosing exact feed location, the two orthogonal degenerate modes are made nearly equal amplitude with a phase difference of 90°. Hence circularly polarized radiation is achieved. Overall size of the patch antenna is determined by the resonant frequency. The edge of the hexagonal patch is designed for a resonant frequency of 2.69 GHz. Due to the central slot the resonant frequency is reduced to 2.42 GHz and thus the overall dimension is reduced by a factor of 22.5%.
The photographs of the proposed antennas are depicted in Fig. 2. To design the hexagonal patch, design equations are derived based on the geometry and frequency of operation after computing the guided wavelength \( \lambda_g \), that is the wavelength in the dielectric \( \lambda_g = \frac{\lambda_0}{\varepsilon_{eff}} \), where \( \lambda_0 \) is the free space wavelength and the effective permittivity of the substrate \( \varepsilon_{eff} \) is computed as 4.106.

A parametric study is done by varying the parameter ‘k’, which is the aspect ratio of height ‘d’ to the central width of the central irregular hexagonal slot, keeping ‘b’ constant. It is observed that when the value of k when exceeds 1.5 circularly polarized radiation is exhibited. The realization of circularly polarized radiation is confirmed at \( k = 1.62 \), as the necessary criterion of axial ratio < 3 dB is satisfied and depicted in Figure 4. When \( k = 1.62 \), the least simulated value of axial ratio = 1.8212 dB is obtained with the fabricated prototype and the corresponding axial ratio bandwidth is calculated to be 180 MHz(7.5%).

The surface current distribution simulated at the centre frequency is plotted in Figure 5&6 for RHCP and LHCP antennas respectively. Surface current distribution at \( \varphi = 0^\circ \) is equal in magnitude and opposite in direction to that at \( \varphi = 180^\circ \). Similar is the case of surface current distribution at \( \varphi = 90^\circ \) and at \( \varphi = 270^\circ \). Hence the criterion for circular polarization is satisfied. As the direction of view chosen as +Z-axis, the direction of rotation of current is clockwise and the sense of polarization is confirmed as left hand circular polarization (LHCP) for the feed position at Y. Feed position at X confirms right hand circular polarization (RHCP). Sense of direction of polarization of the fabricated antennas under study is tested using helical antennas designed at the measured resonant frequency 2.42 GHz as per the design methodology in [13] & [14]. The RHCP helical antenna gives more output when tested with RHCP under study and vice versa.
Graphs plotted in Figure 7 confirm the directions of sense of polarization of the LHCP and RHCP antennas under study. Hexagonal shape is preferred for the antennas because it has more bandwidth compared to rectangular and circular patches [15].

Measured and simulated bore sight radiation patterns of RHCP and LHCP antennas are depicted in Figure 8 and found to be in good agreement. The comparison of measured values of the antenna is tabulated in Table I. More size reduction is due to the increased electrical length which is accounted by the shape of the patch and the slot. Increased axial ratio bandwidth is accounted by the choice of feed point and the aspect ratio of the slot. More impedance bandwidth is due to the choice of feed location and shape of the patch.

The authors have experimentally proved in [14] that when the patch shape is dodecagonal, gain is slightly less (4.82 dBi – 4.67 dBi), ARBW is 5.5% and when the shape is hexagonal with elliptical and circular slots the gain is 4.5 dBi and ARBW is 5.8% [15]; both designed for the same resonant frequency 2.45GHz.

## Appropriateness of the antenna for RFID reader applications at 2.45GHz

The RHCP antenna prototype offers a 10 dB impedance bandwidth of 130 MHz (2.3645 GHz– 2.4965 GHz) and 3 dB ARBW of 180 MHz (2.32 GHz– 2.50 GHz) and a gain of 4.91 dBi. Similarly, the LHCP antenna prototype offers a 10 dB impedance bandwidth of 125 MHz (2.5415 GHz– 2.6165 GHz) and 3 dB ARBW of 181.2 MHz (2.3312 GHz – 2.5124 GHz) and a gain of 4.91 dBi. These values are in compliance with standards of parameters for air interface communications for RFID applications at 2.45 GHz [16].

### V. CONCLUDING REMARKS

A novel design of a single feed circularly polarized regular hexagonal patch antenna with irregular hexagonal slot has been designed, simulated and experimentally investigated. The introduction of central hexagonal slot perturbation method is found to be effective. The antennas provide stable symmetrical patterns with wide angle half power beam widths, good impedance bandwidths, circular polarization characteristics and reasonable peak gain values. The antennas are compact, simple to design cost effective and suitable for wide angle coverage RFID reader applications at 2.45 GHz.

Prakash K.C passed his M.Sc Degree in Electronics Science from Cochin University of Science and Technology, Kerala, India, in 1993, with third rank. He has got 22 years of teaching experience in Electronics and holds the designation of Associate Professor in in Sree Ayyappa College, Eramallikkara; a Kerala Govt. Aided college affiliated to the University of Kerala. Currently he is engaged in research under the faculty development programme of UGC, in the area of microwave antennas for RFID applications. He has got 1 international ,1 national journal and four international conference publications to his credit. He is a Fellow of IETE. His areas of interest include RFID CP antennas, metamaterial, energy harvesting etc.

Vinesh P V received the B.Sc. degree in electronics from the University of Kannur, India, and the M.Sc. degree in Electronics from the MES College Erumely, Kottayam, India, in 2004 and 2006, respectively. He is currently working towards the Ph.D. degree at Cochin University of Science and Technology (CUSAT), Kochi, India. His research interests include designing of multiband antennas, planar inverted F antennas, ZOR antenna etc.

Vivek R received the B.Sc. degree and the M.Sc. degree in electronics from University of Calicut, India, in 2008 and 2010, respectively. He is currently working towards the Ph.D. degree at Cochin University of Science and Technology (CUSAT), India. His research interests include designing of multiband antenna, folded/loop antenna, PIFA antennas, chipless RFID, metasurfaces and UWB antennas.

Mohammad Ameen received his B.Tech degree and M.Tech degree in Electronics and Communication Engineering from Mahatma Gandhi University, Kerala, in 2012 and 2014, respectively. He has 1 year of research experience in Microwave field. Currently he is a Senior Research Fellow in CSIR (New Delhi) funded project at Department of Electronics, Cochin University of Science and Technology, Cochin, Kerala. He has got one international journal and four international conference publications to his credit. His research interests include high gain antennas and MIMO antennas.

Vasudevan K. took PhD in 1982 in Microwave antennas and joined as lecturer in Cochin University of science and technology in 1985. He is a professor in this University since 1995. He was head of department of Electronics from 2004 to 2010 and Dean, faculty of technology during 2010 to 2013. Currently, he is a CSIR Emeritus scientist in Cochin University. He has more than 220 publications in International journals and conference proceedings and has more than 1200 citations and an h-index of 19. He has been an investigator for about 20 major projects from various agencies having a total outlay of 30 crores of rupees. He has chaired and presented papers in several IEEE international conferences abroad. He is a senior member of IEEE and Fellow of IETE.
