# Simulation of Plasticity of Copper(II) Coordination Polyhedron: Empirical Force Field Model with Distorsion Coordinate Potential 

Jasmina Sabolović and Nenad Raos<br>Institute for Medical Research and Occupational Health, University of Zagreb, 41001 Zagreb, Croatia, Yugoslavia<br>and<br>Kjeld Rasmussen<br>Chemistry Department, Technical University of Denmark, DK-2800 Lyngby, Denmark

## Received September 12, 1988

In order to reproduce the geometry of tetracoordinated copper(II) chelates with a »distorted« coordination polyhedron (planar/ /tetrahedral), two new empirical functions for the calculation of the conformational potential were introduced. The first depends on the distorsion coordinate $\beta$, defined as an angle between bisectors of two valence angles around the central atom. The second function is a two-well valence angle bending potential for valence angles around copper, with minima at $90^{\circ}$ and $109.47^{\circ}$.

The new functions were tested on bis-( $N, N$-dimethylvalinato)copper(II). A consistent force field (CFF) calculation with the new functions yielded the correct geometry of copper coordination, i. e. a distorted tetrahedron. The valence angles around copper ( N -$-\mathrm{Cu}-\mathrm{N}, \mathrm{O}-\mathrm{Cu}-\mathrm{N}$ and $\mathrm{O}-\mathrm{Cu}-\mathrm{O}$ ) were reproduced fairly well with root-mean square deviation with respect to the crystal structure of $3.20^{\circ}$ and $3.73^{\circ}$ for the model with a two-well and the model with a quadratic valence angle bending potential, respectively. The measured diastereoselectivity (Gibbs energy difference between $\mathrm{Cu}(\mathrm{L}-\mathrm{ligand})_{2}$ and $\mathrm{Cu}(\mathrm{L}-\mathrm{ligand})$ (D-ligand)) was reproduced within $3 \mathrm{~kJ} \mathrm{~mol}^{-1}$.

## INTRODUCTION

A well known property of copper(II) complexes is the plasticity of their coordination sphere ${ }^{1,2}$. This means that they do not usually form »regular" (planar or tetrahedral) coordination polyhedra. The phenomenon can be manifested both geometrically (structurally) and thermodynamically. Copper coordination geometry strongly depends on both the bonded and non-bonded interactions; therefore, some copper complexes can form crystal modifications differing in coordination geometry (distorsion isomerism ${ }^{3}$ ). In addition to these structural effects, the plasticity of the coordination sphere causes a weakening of the diastereoselectivity effects* in copper chelates in comparison

[^0]with complexes having more rigid coordination (e.g. cobalt and nickel(II) complexes ${ }^{4}$ ).

Our principal aim is to develop a force field (i. e. empirical functions for conformational or strain energy) which should reproduce both the structural and thermodynamical properties of copper(II) chelates, as well as properties of other metal chelates with non-rigid coordination. Our first attempt to estimate the diastereoselectivity effect in copper(II) complexes with $N$-alkylated amino acids $^{5}$ demonstrated too big a difference in energy between MLL and MDL complexes of $N, N$-dimethylvaline. This discrepancy, which was later shown to hold true also for a similar complex, bis-( $N, N$-dimethylisoleucinato)copper(II) ${ }^{6}$, was attributed to the fact that the parameters holding ligand atoms in plane were too strong ${ }^{5,7}$. This is not very surprising because we used the same empirical parameters as for more rigid cobalt(III) and chromium(III) complexes ${ }^{8,11}$. In our first attempt to simulate the geometry of tetracoordinated copper(II) complexes we added two apically placed »dummy< atoms to hold copper and ligand atoms in plane (»dummy« atom model $)^{9}$. "Softening« the force field, i.e. putting the smaller values for angle bending, $k_{\Theta}$, parameters around copper, gave acceptable results with respect to energy ${ }^{7}$, but wrong results with respect to geometry: attempts to reproduce the crystal geometry of bis-(L-N,N-dimethylvalinato)copper(II)** coordination polyhedron yielded a distorted pyramid instead of a distorted tetrahedron ${ }^{10}$.

To achieve a better reproduction of copper(II) coordination geometry, we have introduced a new empirical potential depending on distorsion angle $\beta$ (Figure 1). Angle $\beta$ remains unchanged during the transition from planar to tetrahedral coordination and it causes an additional strain in the molecule for pyramidal distorsion. Therefore, the new models (denoted as Model 1 and Model 2) based on that potential would yield tetrahedral distorsion instead of the pyramidal one.

Figure 1. Distortion angle $\beta$ is defined as an angle between the bisectors of angles OMN and $\mathrm{O}^{\prime} \mathrm{MNN}^{\prime}$ (M denotes the central atom), Y and $\mathrm{Y}^{\prime}$ are »dummy" atoms needed in constructing the angle.

[^1]
## METHODS

The conformational (strain) potential energy was calculated from the basic formula:

$$
\begin{align*}
V= & (1 / 2) \sum_{\mathrm{i}}^{\sum} k_{\mathrm{b}, \mathrm{i}}\left(b_{\mathrm{i}}-b_{0, \mathrm{i}}\right)^{2}+1 / 2 \sum_{\mathrm{j}} k_{\Theta, \mathrm{j}}\left(\Theta_{\mathrm{j}}-\Theta_{0, \mathrm{j}}\right)^{2}+1 / 2 \sum_{\mathrm{k}}^{\sum V_{\mathrm{n}}}\left(1 \pm \cos n \varphi_{\mathrm{k}}\right)+ \\
& +\sum\left(A_{1} \exp \left(-B_{1} r_{\mathrm{j}}\right)-C_{1} r_{1}^{-6}\right)+1 / 2 \Sigma k_{\chi \cdot \mathrm{m}} \%_{\mathrm{m}}^{2}+1 / 2 k_{\beta}\left(\beta-\beta_{0}\right)^{2}+V_{\mathrm{NMO}} \tag{1}
\end{align*}
$$

in which $b, \Theta, \varphi$ and $\chi$ stand for bond lengths, valence, torsional and out-of-plane angles, respectively; $r$ is non-bonded distance, $k_{\mathrm{b}}$ is an empirical parameter for bond stretching and $k_{\Theta}$ for valence angle bending. Torsional interactions were determined with parameters $V_{\mathrm{n}}$ and $n$ (height and multiplictiy of torsional barrier, respectively) and non-bonded interactions were computed from a Buckingham function with parameters $A, B$ and $C$. In addition, the out-of-plane deformation potential for the carboxyl group with quadratic function dependent on parameter $k_{x}$ and distorsion potential (parameters $k_{\beta}$ and $\beta_{o}$ ) was also computed. The last term in equation (1) is angle-bending potential for angles $\mathrm{N}-\mathrm{Cu}-\mathrm{O}$ which can be quadratic:

$$
\begin{equation*}
V_{\text {NMO }}=(1 / 2) k_{\theta}\left(\theta-\theta_{0}\right)^{2} \tag{2}
\end{equation*}
$$

(Model 1) or in the form of cosine power series (Model 2), see below. Model 1 has a minimum for $\mathrm{N}-\mathrm{Cu}-\mathrm{O}$ angles only at $\Theta=90^{\circ}$ (planar configuration). Conversely, Model 2 has two minima for $\mathrm{N}-\mathrm{Cu}-\mathrm{O}$ angles which correspond to planar $\left(\Theta_{01}=90^{\circ}\right)$ and tetrahedral $\left(\Theta_{\mathrm{s} 2}=109.47^{\circ}\right)$ configurations. Therefore, with Model 2 both configurations of copper coordinations (planar and tetrahedral) are possible.

The parameters were the same as those used in our first paper ${ }^{9}$ with the exception of $\mathrm{C}-\mathrm{N}-\mathrm{C}$ bending parameters which were taken to be equal to the parameters for $\mathbf{C}-\mathbf{C}-\mathbf{C}$ bending. Parameters for the valence angle bending around the copper atom (angles $\mathrm{N}-\mathrm{Cu}-\mathrm{O}$ ) and those for distorsion angle potential were determined separately (see Results and Discussion). Empirical constant $k_{x}$ was taken to be $100 \mathrm{kcal} \mathrm{mol}{ }^{-1} \mathrm{rad}^{-2}$. Calculations were performed by the program developed by Kj . Rasmussen and coworkers ${ }^{11,12}$ which was further modified to cope with new empirical potentials.

Distorsion angle (Figure 1) is calculated as a »valence« angle $\mathrm{Y}-\mathrm{M}-\mathrm{Y}$, where Y and Y' are »dummy« atoms placed on the bisector of angles OMN and O'MN', respectively, and IVI is the central (copper) atom.

The coordinates of »dummy« atom $Y$ are taken to be:

$$
\begin{equation*}
x_{\mathrm{iY}}=(1 / 2)\left(x_{\mathrm{iO}}+a x_{\mathrm{iN}}\right) \quad \mathrm{i}=1 \ldots 3 \tag{3}
\end{equation*}
$$

where $x_{\mathrm{io}}$ and $x_{\mathrm{iN}}$ are cartesian coordinates of O and N atoms (origin of the frame is the central atom $\mathbb{M}$ ). Variable $a$ is defined as:

$$
\begin{equation*}
a=b_{\mathrm{MO}} / b_{\mathrm{MN}} \tag{4}
\end{equation*}
$$

where $x_{\mathrm{iO}}$ and $x_{\mathrm{in}}$ are cartesian coordinates of O and N atoms (origin of atom $\mathrm{Y}^{\prime}$ the variables $x_{\mathrm{iY}}{ }^{\prime}$ and $\alpha^{\prime}$ are defined in the same way).

Denoting by $l$ and $l$ ' the lengths of the »bonds« $\mathrm{M}-\mathrm{Y}$ and $\mathrm{M}-\mathrm{Y}^{\prime}$, the distorsion angle $\beta$ can be expressed as:

$$
\begin{equation*}
\cos \beta=\frac{\sum_{\mathrm{i}=1}^{3} x_{\mathrm{iY}} x_{\mathrm{iY}} \mathrm{Y}^{\prime}}{l l^{\prime}} \tag{5}
\end{equation*}
$$

Such a formulation of the distorsion angle enables us to use the existing subroutines in our conformational program for calculating energies and their differentials with respect to valence angles.

Two-well angle bending potential for the NMO angles (Model 2) was calculated from the polynomial function of the general form:

$$
\begin{equation*}
V_{z}=a z^{4}+b z^{3}+c z^{2}+d z+e \tag{6}
\end{equation*}
$$

where $z=\cos \Theta$. Choosing paremeters $\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}$, and e so that function (6) has two minima ( $\Theta_{01}=90^{\circ}, \Theta_{02}=109.47^{\circ}$ ) and satisfies the conditions $V(0)=$ $=0$ and $d^{2} V_{z} /\left.d z^{2}\right|_{\Theta=\Theta_{01}}=k_{z}>0$, the equation (6) can be rewritten in the form:

$$
\begin{equation*}
V_{z}=9 / 2\left(k_{z}-54 h\right) z^{4}+3\left(k_{z}-36 h\right) z^{3}+1 / 2 k_{z} z^{2} \tag{7}
\end{equation*}
$$

where $h$ is the difference in energy between two minima and $k_{z}$ is an empirical parameter.

Function (7) has a maximum at a point:

$$
\begin{equation*}
z_{\max }=\frac{-k_{z}}{6\left(k_{z}-54 h\right)} \tag{8}
\end{equation*}
$$

If both minima have the same energy (i.e. $h=0$ ), line $z=z_{\max }$ should be the symmetry axis of function (7).

Root-mean-square deviation between crystal and theoretical structures was calculated from:

$$
\begin{equation*}
\varepsilon_{\text {r.m.s. }}(\Delta X)=\left(1 / N \sum_{i=1}^{N}\left(\Delta X_{i}\right)^{2}\right)^{1 / 2} \tag{9}
\end{equation*}
$$

where $X$ stands for the angles around copper (valence angles, $\Theta$, distorsion angle $\beta$ and »torsional angle« $\varphi$ (ONN'O')) when comparing the copper coordination geometry, or for interatomic distance, $r$, when checking the overall similarity. Mark $\Delta$ denotes the difference between the values of the observable $X$ in two structures.

The average Gibbs energy of a diastereomer (MLL or MDL) was calculated from the formula:

$$
\begin{equation*}
\langle G\rangle=\Sigma w_{\mathrm{i}} G_{\mathrm{i}} / \Sigma w_{\mathrm{i}} \tag{10}
\end{equation*}
$$

where $G_{\mathrm{i}}$ denotes the Gibbs energy of the i-th conformer, and $w_{\mathrm{i}}$ stands for the statistical weight calculated from the Boltzmann formula. Details of calculations were given elsewhere ${ }^{9}$.

## RESULTS AND DISCUSSION

In order to test our new models (Model 1 and Model 2), we tried to reproduce both the crystal geometry ${ }^{10}$ and the observed diastereoselectivity (enantioselectivity) ${ }^{13}$ of bis-( $N, N$-dimethylvalinato)copper(II). The most critical
parameters ( $k_{\text {Nмо }}, k_{\mathrm{z}}$ and $k_{\beta}$ ) were varied until the best agreement (expressed as $\varepsilon_{\text {r.m.s. }}(\Delta \Theta, \Delta \beta, \Delta \varphi)$ was obtained (footnote to Table III). Both models yielded the best agreement for $k_{\beta}=37.5 \mathrm{kcal} \mathrm{mol}^{-1} \mathrm{rad}^{-2}$ showing amlost the same values of r.m.s. deviation (Table I).

* All values are expressed in ${ }^{\circ}$. For definition of models see Methods.

Both theoretical structures had the correct geometry of a copper coordination polyhedron (i.e. a distorted tetrahedron) which was not possible to obtain with the »dummy« atom model (Figure 2), but the checking of the overall similarity (expressed as $\varepsilon_{\text {r.m.s. }}(\Delta r)$ ) between the crystal and theoretical struc.tures (Table II) yielded essentially the same results for all models.

The conformation of one of the chelate rings (Ring 2) was better reproduced than that of the other, Ring 1 (for the definition of the rings see Figure $3)$. Even the values of $\varepsilon_{\text {r.m.s. }}(\Delta r)$ were almost the same: $0.087 \AA$ (Model 1) and $0.089 \AA$ (Model 2) for Ring $1\left(0.085 \AA\right.$, »dummy" atom model ${ }^{10}$ ) and $0.059 \AA$

TABLE II
Comparison of the Experimental and Theoretical Structure of Bis-(L-N,N-dimethylvalinato)copper(II)*

[^2](Model 1) and $0.061 \AA$ «Model 2) for Ring $2\left(0.053 \AA\right.$, »dummy« atom model ${ }^{19}$ ). The overall similarity between the whole molecular crystal and the theoretical structures (Table II and Figure 3) is also comparable with the results obtained

Figure 2. Shapes of copper(II) coordination polyhedron of bis-( $1,-N, N$-dimethylvalinato)copper(II): crystal structure [I] ${ }^{10}$, »dummy« atom model FF2 [II] ${ }^{10}$, Model 1 [III] and Model 2 [IV].
with the »dummy« atom model $\left(\varepsilon_{\text {r.m.s. }}(\Delta r)=0.14 \AA\right.$ v.s. $\left.0.13 \ldots 0.17 \AA^{10}\right)$. It seems that our Model 1 better reproduces the overall molecular geometry than Model 2, but the differences are practically negligible. Also, new models yielded a slightly different conformation of chelate rings. In contrast to the »dummy« atom model ${ }^{9,10}$ which after the minimization of conformational energy yielded exactly the same conformation at both chelate rings, our new models lead to chelate rings differing from each other by $0.001 \AA$, in $\varepsilon_{\text {r.m.s. }}(\Delta r)$ or $0.02^{\circ}$ in r.m.s. deviations for torsional angles. These differences are at least one order of magnitude less than the differences between the ring conformations observed in the crystal structure ${ }^{10}\left(\varepsilon_{\text {r.m.s. }}(\Delta r)=0.07 \AA\right.$ error in estimation of torsional angles from 0.2 to $8^{\circ}$ ). Therefore, it stands to reason that the observed difference between chelate ring conformations in the crystal structure is caused by intermolecular interactions rather than by intramolecular ones.

The estimated diastereoselectivity (enantioselectivity) depends slightly on the procedure of calculation. It can be calculated (neglecting the vibrational contribution to Gibbs energy) from the conformational potential (Table III),

[^3]or more accurately, from the Gibbs energy (Table IV). For prediction of energy, the new models appear to be less successful than the best »dummy" atom model (Tables III, IV), but undoubtedly better than the first »dummy" atom model ${ }^{5}$, with too strong parameters around copper, which yielded planar geometry and very high diastereoselectivity ( $9.47 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ).

| :--- | :--- | :--- |

Experimental value ${ }^{13}$
$2.9 \ldots 4.0$

* See footnote to Table III. T $=298.16 \mathrm{~K}$. Zero points: $1061.91 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for »dummy«
atom model, $1097.19 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for Model 1 , and $1100.89 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for Model 2 .

The fact that virtually the same results were obtained by models differing in the analytical form of potential $V_{\text {ммо }}$ can be accounted for by the shape of coordination polyhedron in the crystal structure which is more planar than tetrahedral (the maximum value of NMO angle is $97.1^{\circ}$ ), i. e. all the final values of NMO angles are placed on the same "side« of the two-well potential curve. The only conformer which has the NMO angle values closer to tetrahedral geometry, denoted as 3-3LD (Table II), has such high energy that its influence on the overall stability of the complex is negligible.

In conclusion we can state that the newly proposed models with the distorsion potential proved to be capable of reproducing fairly well the geometry and energy of bis-( $N, N$-dimethylvalinato)copper(II). Our future research should show whether they are applicable to other distorted structures.

## SAZ̆ETAK

Simulacija plastičnosti koordinacijskog poliedra bakra(II): model empirijskog polja sila s potencijalom ovisnim o distorzijskoj koordinati

J. Sabolović, N. Raos i Kj. Rasmussen

Da bi se reproducirala geometrija tetrakoordiniranih kelata dvovalentnog bakra s »distordiranim« koordinacijskim poliedrom (prelazni oblici između tetraedra i planarne konfiguracije) uvedene su dvije nove empirijske funkcije za proračun konformacijskog potencijala. Prva funkcija ovisi o distorzijskoj koordinati $\beta$, deffiniranoj kao kut između polovišta dvaju valencijskih kuteva oko centralnog atoma. Druga funkcija je potencijal promjene valencijskog kuta s dva minimuma (pri 90 i $109,47^{\circ}$ ) za kuteve oko bakra.

Nove funkcije iskušane su na molekuli bis-( $N, N$-dimetilvalinato)bakra(II). Metodom usklađenog polja sila (consistent force field, CFF) računski je polučena ispravna geometrija bakrove koordinacije, tj. distordirani tetraedar. Valencijski kutevi oko bakra ( $\mathrm{N}-\mathrm{Cu}-\mathrm{N}, \mathrm{O}-\mathrm{Cu}-\mathrm{N}$ i $\mathrm{O}-\mathrm{Cu}-\mathrm{O}$ ) vrlo su dobro reproducirani, dajući korijen razlika srednjih kvadrata odstupanja od kristalne strukture u iznosu od $3,20^{\circ}$ (model s kvadratnom funkcijom za potencijal promjene valencijskih kuteva) i $3,73^{\circ}$ (potencijal s dva minimuma). Izmjerena diastereoselektivnost [razlika Gibbsove energije između $\mathrm{Cu}\left(\mathrm{L}\right.$-ligand) $\mathbf{2}^{\text {i }} \mathrm{Cu}(\mathrm{L}$-ligand)(D-ligand)] reproducirana je unutar $3 \mathrm{~kJ} \mathrm{~mol}^{-1}$.

[^0]:    * Defined as $\Delta G=-R T \ln \left(\beta_{\mathrm{MLL}} / \beta_{\mathrm{MDL}}\right)$, L and D denoting ligand enantiomers and $\beta$ cumulative stability constants.

[^1]:    ** $N$,N-dimethylvaline: $N$,N-dimethyl-3-methyl-2-aminobuthanoic acid.

[^2]:    * Only non-hydrogen atoms are taken into account. Theoretical structures correspond to minimum 6-6LL (Table III, IV).

[^3]:    * All energy values are expressed in $\mathrm{kJ} \mathrm{mol}^{-1}$. Statistical weights are given in parentheses. The »dummy« atom model corresponds to force field FF2, ref. 10. Minima of conformational energy are denoted as in ref. 5. Parameters: $\mathrm{k}_{\beta}=37.5$ kcal $\mathrm{mol}^{-1} \mathrm{rad}^{-2}, \beta_{0}=180^{\circ}$; Model $1 \mathrm{k}_{\text {Ммо }}=250 \mathrm{kcal} \mathrm{mol}^{-1}$, $\mathrm{rad}^{-2} ;$ Model $2 \mathrm{k}_{z}=500$ kcal $\mathrm{mol}^{-1}, \mathrm{~h}=0$ (eq. 7). Zero points: $26.92 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for »dummy" atom model, $32.91 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for Model 1, and $34.40 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for Model 2. For definition of Model 1 and Model 2 see Methods. Diastereoselectivity was calculated from energy of all 21 conformers.
