Topological Resonance Energies of Annulenes*

I. Gutman, M. Milun**, and N. Trinajstić

Theoreticai Chemistry Group, The Ruder Bošković Institute, P.O.B. 1016, 41001 Zagreb, Croatia, Yugoslavia

Received September 20, 1976

The recently developed concept of topological resonance energy, \( T_{RE} \), (the optimal non-parametric realization of Dewars-type resonance energy, \( DRE \)) is applied to neutral (odd and even) and charged annulenes. Analytical expressions for \( T_{RE} \) of neutral annulenes, their mono- and di-cations, and mono- and di-anions are derived. The results obtained are in good agreement with experimental findings for both neutral and charged annulenes.

INTRODUCTION

Annulenes, the monocyclic fully conjugated hydrocarbon family of general formula \( \text{C}_N\text{H}_N \) (\( N = 3, 4, 5, \ldots \))\(^1\), represent an interesting class of unsaturated cyclic compounds because of their complex chemical and structural properties.\(^2\) The important development in the chemistry of annulenes started with Hückel's \( 4m+2 \) rule\(^3\), according to which the annulenes with \( 4m+2 \) \( \pi \)-electrons should exhibit properties different from the annulenes containing \( 4m \) \( \pi \)-electrons. However, in the Hückel time, the only annulenes known were \([6]\) annulene (benzene), classical aromatic compound, and the non-aromatic \([8]\) annulene (cyclooctatetraene, COT).\(^4\) Hückel's rule, thus, had a great impact on the development of the annulene chemistry because a number of annulene syntheses are planned in order to prove or disapprove this rule.\(^5\) Simultaneously with preparative work, various theoretical indices of aromaticity (\( DRE \), \( KK \), \( REPE \), \( A \), \( RE \), etc.) were derived and applied to annulenes in order to predict their aromatic character and to investigate whether Hückel's rule holds for an arbitrary size of the annulene ring or whether there is a critical size at which the \( 4m+2 \) rule breaks down. Longuet-Higgins and Salem\(^11\) predicted the \([18]\) annulene ring system to be of a critical size at which \([4m+2]\)-annulenes behave like cyclic polyenes with alternating single and double bonds. However, Dewar and Gleicher\(^5\) used a modification\(^12\) of Pople's SCF \( \pi\)-MO method\(^13\) parametrized to reproduce the ground state properties. They have found that the critical size at which the bond alternation occurs is between \([22]\)- and \([26]\)-annulene. NMR studies\(^14\) support this result according to which the \([4m+2]\)-annulenes up to \( m = 5 \) are aromatic, whereas higher \([4m+2]\)-annulenes behave as non-aromatic species. Consequently, any theoretical treatment of annulenes must differentiate between \([4m+2]\) and \([4m]\)-

* Contribution No. 195 of the Laboratory of Physical Chemistry.
** Permanent address: Research Department, Chromos-Katran-Kutrillin, Žitnjak b.b., 41000 Zagreb.
classes for \( m \) being small and must indicate the convergence between the two classes for \( m \) being large.

Recently, we have introduced\(^{15}\) a new* theoretical index of aromaticity, named topological resonance energy, \( TRE \), which solely depends on the molecular topology and does not require any additional parameter (usually needed by other theoretical methods\(^5\)-\(^{16}\)). We therefore thought that annulenes, because of their unique topology (cycles of degree two)\(^{16}\) and very specific properties, would be a good class of important organic compounds to test the \( TRE \) concept. Besides, \( TRE \) values can be evaluated for odd-membered annulenes and for annulene ions. Dewar-type theoretical indices, earlier proposed, could not embrace annulene radicals and ions in a simple way. We believe that the possibility of studying all annulene ring systems justifies the present investigation.

**THEORETICAL APPROACH**

Annulenes are a very simple class of conjugated structures. They exhibit a number of topological regularities. In addition, annulenes possess a high symmetry which allows one to write analytical expressions for their energies and \( TRE \) indices.

The starting point in deriving \( TRE \) expressions of annulene systems is as follows,

\[
TRE = E_\pi ([N] \text{annulene}) - E_\pi (\text{reference structure}) \quad (1)
\]

where the terms on the right side of eq (1) denote the total HMO \( \pi \)-eletron energy (in units \( \beta \)) of \([N]\) annulene and the corresponding reference structure, respectively. In our theoretical approach\(^{15}\), the reference structure contains all acyclic contributions to \( E_\pi \) of a cyclic structure. Thus, \( TRE \) represents only cyclic contributions to \( E_\pi \). This definition of resonance energy is the optimal non-empirical realization of Dewar's concept\(^5\) of resonance energy.

Analytical expressions for \( E_\pi ([N] \text{annulene}) \) are known\(^9\),\(^{17},\(^{18}\)

\[
E_\pi ([N] \text{annulene}) = \begin{cases} 
2 (\cot \Theta - \tan \Theta) & ; N = 4m \\
2 \cot \Theta \cos \Theta & ; N = 4m + 1 \text{ or } N = 4m + 3 \\
2 (\cot \Theta + \tan \Theta) & ; N = 4m + 2 
\end{cases} \quad (2)
\]

where \( \Theta = \pi/2N \).

The \( E_\pi \) (reference structure) is derived in the following way. The molecular graph representing \([N]\) annulene is a cycle \( C_N \) with \( N \) vertices (see Figure 1). Let us denote the edge in \( C_N \) by \( e \). The excising of the edge \( e \), connecting vertices \( N \) and 1, from \( C_N \) leads to chain \( L_N \) with \( N \) vertices, while removal of \( e \) together with incident vertices (e.g. \( N \) and \( N-1 \)) produces chain \( L_{N-2} \) with \( N-2 \) vertices (see Figure 1). Let us now consider the possible ways of selecting \( j \) non-neighbouring edges in the graph \( C_N \). This may be done in two ways: (i) edge \( e \) is not among \( j \) edges selected. There are \( g_j (L_N) \) selections of this kind. (ii) edge \( e \) is among \( j \) edges selected. There are \( g_{j-1} (L_{N-2}) \) selections of this kind. Hence,

\[
\begin{align*}
g_j (C_N) & = g_j (L_N) + g_{j-1} (L_{N-2}) \\
& (3)
\end{align*}
\]

* Independently, Aihara (J.-I. Aihara, J. Amer. Chem. Soc. 98 (1976) 2750) has developed similar index of aromaticity.
Note the definition of the polynomial $P(G, x)$,

$$P(G, x) = \sum_j (-1)^j g_j(G) x^{2j}$$  \hspace{1em} (4)

where $g_j(G)$ is a number of possible selections of $j$ mutually non-incident edges in the molecular graph. Thus, it follows from the above considerations

$$\Gamma(C_N, x) = \Gamma(L_N, x) - \Gamma(L_{N-2}, x)$$  \hspace{1em} (5)

The $I'$ polynomial is defined in such a way that in the acyclic graph it is identical to the characteristic polynomial ($P$-polynomial) of the same graph$^{19}$. Because of this

$$\Gamma(C_N, x) = P(L_N, x) - P(L_{N-2}, x)$$  \hspace{1em} (6)

Since,

$$P(L_N, x) = \frac{\sin (N + 1) t}{\sin t}$$  \hspace{1em} (7)

and introducing $x = 2 \cos t$, it follows directly

$$\Gamma(C_N, x) = 2 \cos N t$$  \hspace{1em} (8)

The roots of the polynomial $I'(C_N, x)$ are given by,

$$\gamma_j = 2 \cos \frac{2j + 1}{2N} \pi; \hspace{.5em} j = 0, 1, \ldots, N - 1$$  \hspace{1em} (9)

The $E_\pi$ (reference structure) is related to the roots of the polynomial $I'(G, x)^{15}$,

$$E_\pi (\text{reference structure}) = \sum_j |\gamma_j|$$  \hspace{1em} (10)

Introducing eq (9) in (10), one obtains

$$E_\pi (\text{reference structure}) = 4 \sum_{j=0}^{\mu} \cos \frac{2j + 1}{2N} \pi$$  \hspace{1em} (11)

where

$$\mu = \begin{cases} 
\frac{N-2}{2} &; N = \text{even} \\
\frac{N-1}{2} &; N = \text{odd}
\end{cases}$$

(12)

This expression can be further simplified using the technique of Polansky²⁹

$$E_n (\text{reference structure}) = \begin{cases} 
2 \cot \Theta / \cos \Theta &; N = \text{even} \\
2 \cot \Theta &; N = \text{odd}
\end{cases}$$

(13)

The final TRE expressions are obtained by substituting eqs (2) and (13) into (1)

$$TRE (\text{[N]annulene}) = \begin{cases} 
2 \left[ \frac{\cos \Theta - 1}{\sin \Theta} - \tan \Theta \right] &; N = 4m \\
2 \frac{\cos \Theta - 1}{\sin \Theta} \cos \Theta &; N = 4m + 1 \\
2 \left[ \frac{\cos \Theta - 1}{\sin \Theta} + \tan \Theta \right] &; N = 4m + 2
\end{cases}$$

(14)

TRE per electron, TRE (PE), and RE⁵⁻¹⁰ indices of [N] annulenes are reported in Table I*

Furthermore, the dependence of TRE (PE) on the ring size is demonstrated in Figure 2.

Analytical expressions for TRE of annulene ions are obtained straightforwardly. Let \((TRE)^0\), \((TRE)^+\), \((TRE)^{++}\), \((TRE)^-\), and \((TRE)^{--}\), respectively denote

![Figure 3.](image)

**DISCUSSION**

Analysis of eq (14) and Figure 2 shows that [4 m + 2]- and [4 m]-annulenes become rapidly non-aromatic compounds with increasing value of $m$ and that the differences between them practically disappear. Thus, [18]-annulene is predicted to be a cyclic polyene ($TRE(PE) = 0.005 \beta$) (a compound is considered non-aromatic if its $TRE(PE) < 0.010 \beta$ and $> -0.010 \beta$). Some other theoretical predictions ($REPE$ index) opposes to our result, but a recent, very thorough MINDO/3 study$^{21}$ of [18] annulene (its geometry was calculated by minimizing the energy with respect to all 102 internal coordinates) indicates negligible $\pi$-electron delocalization. Experimental evidence shows that [18] annulene fails to undergo electrophilic substitution reactions$^{22}$ unless the reaction is carried out under very specific conditions$^{23}$.

The $TRE$ index neglects steric effects. Thus, all annulenes are assumed to be planar. This assumption is not realistic in those annulenes in which the repulsion between the annulene inner hydrogen atoms considerably affects the total molecular energy. For example, [10] annulene ($TRE(PE) = 0.016 \beta$) may appear in two forms (I and II) which are both non-planar$^{24}$. 

![Diagram](image)
The repulsion between the inner hydrogen atoms in [14] annulene ($TRE(PE) = 0.008 \beta$) is smaller than in [10] annulene. [14] annulene is the most stable in the planar form $III^2$.

Bridged [14] annulenes have also been synthesized$^{25}$ and the NMR spectrum of IV, for example, indicates that this compound is diatropic.

This structure is aromatic, because there is no interference from the inner hydrogen atoms which are removed by the bridge. [22]-, [26]-, and [30]-annulene have been prepared$^{2,26,27}$. They differ in their stabilities, [22] annulene ($TRE(PE) = 0.003 \beta$) being the most stable and [30] annulene ($TRE(PE) = 0.002 \beta$) the least stable of these three compounds, however all of them exhibit cyclopolyene characteristics.

A considerable amount of preparative work has also been carried out on [4 m] annulenes. Attempts to make [4] annulene (cyclobutadiene, $TRE(PE) = -0.307 \beta$) are classical examples in this respect$^{28}$. [8] annulene ($TRE(PE) = 0.075 \beta$) is not a planar compound$^2$; its planar form would be a highly unstable anti-aromatic species. [12] annulene ($TRE(PE) = -0.032 \beta$) was synthesized at very low temperature$^{29}$. [16] annulene was also prepared$^{26}$ at 273 K and was observed to be a reasonable stable compound. Similarly, [20] annulene ($TRE(PE) = -0.012 \beta$) and [24] annulene ($TRE(PE) = -0.008 \beta$) are known to exhibit non-aromatic properties$^7,28$. Thus, experimental data for both [4 m] and [4 m + 2] annulenes with large $m$ ($m > 4$) exhibit polyolefinic character and support predictions of the $TRE$ index.

$TRE$ values of odd annulenes, [4 m + 1] and [4 m + 3] annulenes (see Figure 3) indicate that the stability of these systems does not depend on the ring size. Some of these compounds, e.g. $(C_2H_3)^+$, $(C_3H_5)^+$, $(C_4H_7)^+$, $(C_5H_9)^+$, $(C_6H_{11})^{2+}$, and $(C_7H_{13})^{3+}$ were predicted to be aromatic ions and are all prepared in solution$^{34-41}$. All these compounds, follow $4m + 2 \pi$-electron Hückel's rule$^3,42$. It is interesting to note that in the case of cyclooctatetraene (COT) the parent compound and all ions
were prepared except COT⁺. The TRE (PE) index gives the following ordering of COT and its ions

\[ \text{COT}^{+} \approx \text{COT}^{-} > \text{COT}^{0} \approx \text{COT}^{-} > \text{COT}^{0} \]

This result is in full agreement with experimental findings.

Some higher charged annulenes have also been prepared. Thus, \((C_{11}H_{11})^+\), \((C_{12}H_{12})^+\), \((C_{13}H_{13})^+\), \((C_{14}H_{14})^+\), \((C_{15}H_{15})^-\), \((C_{16}H_{16})^-\), \((C_{24}H_{24})^-\) have been prepared recently, though some of them with various substituents and some with bridges. An interesting prediction has been reached for dianions of \([4m]\)-systems. These are predicted to be much more stable (for \(m < 5\)) than the parent compound. Thus, \((C_{11}H_{11})^-\) was observed to be relatively stable. Similarly, \((C_{16}H_{16})^-\) remained unchanged after boiling in tetrahydrofuran-d⁸ at 373 K. Therefore, \([4\,m]\) annulenes could be converted into aromatic dianionic \(4\,m + 2\) \(\pi\)-electron systems. Our TRE (PE) index closely follows these considerable changes in stabilization. (Compare Figures 2 and 3). Similarly, the opposite effect should be expected in the case of \([4\,m + 2]\) annulenes when converted to dianionic \(4\,m\) \(\pi\)-electron systems. A remarkable change appears in the NMR spectrum of \((C_{18}H_{18})^-\) when compared with the parent compound. \((C_{18}H_{18})\) is very paratropic, in accord with a 20 \(\pi\)-electron system.

In all cases studied the TRE (PE) index closely follows experimental findings and thus it proves the predictive power of the topological method used here. However, Dewar's resonance energies, DRE are very useful in the case of neutral even annulenes (TRE index has the advantage over DRE in the case of odd and charged annulenes). It would, therefore be interesting to investigate the relationship between TRE and DRE indices. The \(E_\pi\) (reference structure) of annulene is given by,

\[ E_\pi^{\text{(reference structure)}} = A \, n_+ + B \, n_- \quad (19) \]

where A and B are constants. The values of A and B are 2.00 \(\beta\) and 0.52 \(\beta\), respectively in the approach of Milun et al. and 2.0699 \(\beta\) and 0.4660 \(\beta\), respectively in the Hess and Schaad model. Since \(n_+\) and \(n_- = N/2\) for \([N]\) annulenes, it follows that both approaches give a similar expression for the \(\pi\)-electron energy of the reference structure

\[ E_\pi^{\text{(reference structure)}} = 1.27 \, N \quad (20) \]

\(E_\pi\) (reference structure) in TRE theory is not a linear function of N. However, the following approximations can be used: \(\sin \Theta \approx 0\) and \(\cos \Theta \approx 1\) (these approximations are quite reasonable for large N) in eq (13). Then, it follows

\[ E_\pi^{\text{(reference structure)}} \approx \frac{4}{\pi} \, N = 1.27 \, N \quad (21) \]

Therefore, eqs (20) and (21) are equal. In the DRE approach of Hess and Schaad this equality is conditioned by the particular selection of bond parameters. This also indicates that topology is the backbone of DRE approach, at least for annulenes.

CONCLUSIONS

As it has already been pointed out, the TRE method has several important advantages over the DRE method. These are:
(a) TRE is an optimal non-parametric realization of Dewar’s concept of resonance energy; (b) TRE contains all cyclic and no acyclic contributions to π-electron energy of a molecule; (c) TRE is applicable to an arbitrary conjugated system, and (d) TRE allows a derivation of simple analytical formulae for TRE of both neutral and charged annulenes.

The available experimental data support TRE predictions, so that the TRE method can be considered as a powerful tool for estimating the aromatic stability of annulenes and related compounds.

**SAŽETAK**

**Topološke rezonancijske energije anulena**

I. Gutman, M. Milun i N. Trinajstić

Nedavno razvijena koncepcija topološke rezonancijske energije, TRE (optimalne neparametarske realizacije Dewarove rezonancijske energije), primijenjena je na TRE neutralnih anulena i njihovih mono- i di-kationa i aniona. Dobiveni rezultati dobro se slažu s eksperimentalno nadenim činjenicama, kako za neutralne anulene, tako i za njihove ione.
