PRESENTATIONS OF FEIGIN-STOYANOVSKY’S TYPE SUBSPACES OF STANDARD MODULES FOR AFFINE LIE ALGEBRAS OF TYPE $\mathcal{C}_\ell^{(1)}$

GORAN TRUPČEVIĆ
University of Zagreb, Croatia

Abstract. Feigin-Stoyanovsky’s type subspace $W(\Lambda)$ of a standard $\tilde{g}$-module $L(\Lambda)$ is a $\tilde{g}_1$-submodule of $L(\Lambda)$ generated by the highest-weight vector $v_\Lambda$, where $\tilde{g}_1$ is a certain commutative subalgebra of $\tilde{g}$. Based on the description of basis of $W(\Lambda)$ for $\tilde{g}$ of type $\mathcal{C}_\ell^{(1)}$, we give a presentation of this subspace in terms of generators and relations

$W(\Lambda) \simeq U(\tilde{g}_1^+)/J.$

1. Introduction

B. Feigin and A. Stoyanovsky introduced principal subspaces of standard modules for affine Lie algebras of type $A_1^{(1)}$ and $A_2^{(1)}$ in [12] where they have recovered Rogers-Ramanujan type identities by considering graded dimensions of these subspaces. An important part of their investigation was the knowledge of presentations of these subspaces in terms of generators and relations. Another type of principal subspaces, called Feigin-Stoyanovsky’s type subspaces, was introduced by M. Primc who constructed bases of these subspaces in different cases ([24–26, 18]). These kind of subspaces were further studied by many authors ([28, 15, 10, 11, 1, 13, 14, 2, 4, 5, 17, 30], etc.) and the knowledge of presentation presents an important question in this study ([6–9, 27, 23]).

In our previous works we have described bases of Feigin-Stoyanovsky’s type subspaces of standard modules for affine Lie algebras of type $\mathcal{C}_\ell^{(1)}$ ([3])
and obtained from them basis for the whole standard modules ([3]). In this note we use the description of bases of a Feigin-Stoyanovsky’s type subspaces to give presentations of these subspaces in terms of generators and relations.

2. FEIGIN-STOYANOVSKY’S TYPE SUBSPACES

Let \( g \) be a complex simple Lie algebra of type \( C_\ell \) with a Cartan subalgebra \( \mathfrak{h} \) and a root decomposition \( g = \mathfrak{h} + \sum \mathfrak{g}_\alpha \). Let

\[
R = \{ \pm \epsilon_i \pm \epsilon_j \mid 1 \leq i \leq j \leq \ell \} \setminus \{ 0 \}
\]

be the corresponding root system realized in \( \mathbb{R}^\ell \) with the canonical basis \( \epsilon_1, \ldots, \epsilon_\ell \). Fix simple roots

\[
\alpha_1 = \epsilon_1 - \epsilon_2, \quad \ldots, \quad \alpha_{\ell-1} = \epsilon_{\ell-1} - \epsilon_\ell, \quad \alpha_\ell = 2\epsilon_\ell
\]

and let \( g = \mathfrak{n}_- + \mathfrak{h} + \mathfrak{n}_+ \) be the corresponding triangular decomposition. Let \( \theta = 2\alpha_1 + \cdots + 2\alpha_{\ell-1} + \alpha_\ell = 2\epsilon_1 \) be the maximal root and

\[
\omega_r = \epsilon_1 + \cdots + \epsilon_r, \quad r = 1, \ldots, \ell
\]

fundamental weights (cf. [16]). Fix root vectors \( x_\alpha \in \mathfrak{g}_\alpha \). We identify \( \mathfrak{h} \) and \( \mathfrak{h}^* \) via the Killing form \( \langle , \rangle \) normalized in such a way that \( \langle \theta, \theta \rangle = 2 \).

Let \( \tilde{g} \) be the affine Lie algebra of type \( C^{(1)}_\ell \) associated to \( g \),

\[
\tilde{g} = g \otimes \mathbb{C}[t, t^{-1}] + \mathbb{C}c + \mathbb{C}d,
\]

with the canonical central element \( c \) and the degree element \( d \) (cf. [19]). Let

\[
\tilde{g} = \tilde{n}_- + \tilde{h} + \tilde{n}_+
\]

be a triangular decomposition of \( \tilde{g} \), where \( \tilde{n}_- = n_- + g \otimes t^{-1} \mathbb{C}[t^{-1}] \), \( \tilde{h} = h + \mathbb{C}c + \mathbb{C}d \), \( \tilde{n}_+ = n_+ + g \otimes t \mathbb{C}[t] \). Denote by \( \Lambda_0, \ldots, \Lambda_\ell \) fundamental weights of \( \tilde{g} \).

For \( x \in \mathfrak{g} \) and \( n \in \mathbb{Z} \) denote by \( x(n) = x \otimes t^n \) and \( x(z) = \sum_{n \in \mathbb{Z}} x(n) z^{-n-1} \), where \( z \) is a formal variable.

Let \( L(\Lambda) \) be a standard \( \tilde{g} \)-module with the highest weight

\[
\Lambda = k_0 \Lambda_0 + k_1 \Lambda_1 + \cdots + k_\ell \Lambda_\ell,
\]

\( k_i \in \mathbb{Z}_+ \) for \( i = 0, \ldots, \ell \), and fix a highest weight vector \( v_\Lambda \). Denote by \( k = \Lambda(c) \) the level of \( \tilde{g} \)-module \( L(\Lambda) \), \( k = k_0 + k_1 + \cdots + k_\ell \).

Fix the minuscule weight \( \omega = \omega_\ell = \epsilon_1 + \cdots + \epsilon_\ell \in \mathfrak{h}^* \); then \( \langle \omega, \alpha \rangle \in \{-1,0,1\} \) for all \( \alpha \in R \) and define the set of colors

\[
\Gamma = \{ \alpha \in R \mid \langle \omega, \alpha \rangle = 1 \} = \{ \epsilon_i + \epsilon_j \mid 1 \leq i \leq j \leq \ell \}.
\]

Write

\[
(ij) = \epsilon_i + \epsilon_j \in \Gamma \quad \text{and} \quad x_{ij} = x_{\epsilon_i, \epsilon_j}.
\]

This gives a \( \mathbb{Z} \)-gradation of \( \tilde{g} \); let \( \mathfrak{g}_0 = \mathfrak{h} + \sum_{\langle \omega, \alpha \rangle = 0} \mathfrak{g}_\alpha \), then

\[
\tilde{g} = \tilde{g}_{-1} + \tilde{g}_0 + \tilde{g}_1,
\]
where

\[
\tilde{g}_0 = g_0 \otimes \mathbb{C}[t, t^{-1}] \oplus \mathbb{C}c \oplus \mathbb{C}d, \quad \tilde{g}_{\pm 1} = \sum_{\alpha \in \pm \Gamma} g_0 \otimes \mathbb{C}[t, t^{-1}].
\]

The subalgebra \( \tilde{g}_1 \) is commutative, and \( g_0 \) acts on \( \tilde{g}_1 \) by adjoint action.

Feigin-Stoyanovsky’s type subspace of \( L(\Lambda) \) is a \( \tilde{g}_1 \)-submodule of \( L(\Lambda) \) generated by the highest-weight vector \( v_\Lambda \),

\[
W(\Lambda) = U(\tilde{g}_1) \cdot v_\Lambda = U(\tilde{g}_1^-) \cdot v_\Lambda \subset L(\Lambda),
\]

where \( \tilde{g}_1^- = \tilde{g}_1 \cap \tilde{n}_- \).

We use an exponential notation to describe monomials \( m \in U(\tilde{g}_1^-) = S(\tilde{g}_1^-) \):

\[
m = \cdots x_{i'j'}(-n)^{b_{i'j'}} \cdots x_{ij}(-1)^{a_{ij}}.
\]

It will be clear from the context to which factors exponents \( a_{ij} \)'s, \( b_{ij} \)'s, \( c_{ij} \)'s correspond to.

A monomial \( m \) is said to satisfy difference conditions for \( W(\Lambda) \), DC for short, if for any \( n \in \mathbb{N} \) and \( i_1 \leq \cdots \leq i_t \leq j_t \leq \cdots \leq j_1 \leq i_{t+1} \leq \cdots \leq i_s \leq j_s \leq \cdots \leq j_t \), the exponents of \( x_{ij}(-n) \)'s and \( x_{ij}(-n-1) \)'s in \( m \), denoted by \( a_{ij} \)'s and \( b_{ij} \)'s, respectively, satisfy

\[
b_{i_1j_1} + \cdots + b_{i_tj_t} + a_{i_{t+1}j_{t+1}} + \cdots + a_{i_sj_s} \leq k.
\]

A monomial \( m \) satisfies initial conditions for \( W(\Lambda) \), IC for short, if for every \( i_1 \leq \cdots \leq i_t \leq j_t \leq \cdots \leq j_1 \),

\[
a_{i_1j_1} + \cdots + a_{i_tj_t} \leq k_0 + k_1 + \cdots + k_{j_1-1}
\]

where \( a_{ij} \)'s denote exponents of \( x_{ij}(-1) \) in \( m \).

**Theorem 2.1** ([3]). The set

\[
\{mv_\Lambda \mid m \text{ satisfies DC and IC for } W(\Lambda) \}
\]

is a basis of \( W(\Lambda) \).

3. **Presentation of Feigin-Stoyanovsky’s type subspaces**

Difference conditions are consequences of the adjoint action of \( g_0 \) on the vertex-operator relation

\[
x_\theta(z)^{k+1} = 0,
\]

or, equivalently, on a family of relations

\[
\sum_{n_1, \ldots, n_k \geq 1 \atop n_1 + \cdots + n_k = N} x_{11}(-n_1) \cdots x_{11}(-n_k) = 0, \quad \text{for } N \geq k + 1
\]

on \( L(\Lambda) \) (cf. [3]; see also [21, 22, 20]).

Root vectors of \( g \) can be chosen so that the action of \( g_0 \) on \( g_1 \) is given by

\[
[x_{-\alpha}, x_{ij}] = x_{i+1,j}, \quad [x_{-\alpha}, x_{ij}] = x_{i,j+1}, \quad [x_{-\alpha}, x_{ii}] = 2x_{i,i+1}
\]
Then one easily sees that the adjoint action gives the following family of relations on $L(Λ)$:

$$
\sum_{i_1, \ldots, i_k, j_1, \ldots, j_k = 1}^{N} C_{ij} x_{i_1j_1} (-n_1) \cdots x_{i_kj_k} (-n_k) = 0,
$$

for some nonnegative integers $C_{ij}$, where the sum runs over all such partitions $i,j$ of a multiset $\{1^{m_1}, \ldots, \ell^{m_\ell}\}$, $m_1 + \cdots + m_\ell = 2(k+1)$ (cf. [3]).

One obtains the difference conditions by finding minimal monomials of these relations, the so called leading terms of relations, whose multiples can be excluded from the spanning set. For this, a linear order on monomials is introduced. Define a linear order on the set of colors $Γ$: $(i'j') < (ij)$ if $i' > i$ or $i' = i, j' > j$. On the set of variables $Γ^\gamma = \{x_\gamma(n) | \gamma \in Γ, n \in \mathbb{Z}_-\}$ define a linear order by $x_\gamma(n) < x_\beta(n')$ if $n < n'$ or $n = n', \alpha < \beta$. For monomials, assume that factors descend from right to left, then use a lexicographic order (compare factors the greatest to the lowest one). Order $<$ compatible with multiplication (see [24, 30]):

if $m_1 < m_2$ then $mm_1 < mm_2$, for $m, m_1, m_2 \in U(\tilde{g}_1)$.

For initial conditions consider decompositions

$$
Λ = Λ^{(r)} + Λ_{(r)}, \quad Λ^{(r)} = k_0 Λ_0 + \cdots + k_{r-1} Λ_{r-1}, \quad Λ_{(r)} = k_r Λ_r + \cdots + k_t Λ_t,
$$

for $1 \leq r \leq t$. By $v^{(r)}$ and $v_{(r)}$ denote highest weight vectors of the associated standard modules $L(Λ^{(r)})$ and $L(Λ_{(r)})$ of level $k^{(r)} = k_0 + \cdots + k_{r-1}$ and $k_{(r)} = k_r + \cdots + k_t$, respectively. Then $L(Λ)$ can be embedded in a tensor product $L(Λ) \subset L(Λ^{(r)}) \otimes L(Λ_{(r)})$. Since $x_{ij}(-1)v_{(r)} = 0$ if and only if $j \leq r$ (cf. [3]), we have

$$
m(v^{(r)} \otimes v_{(r)}) = (mv^{(r)}) \otimes v_{(r)}
$$

for $m = x_{i_1j_1} (-1) \cdots x_{i_sj_s} (-1)$ such that $j_s \leq r, 1 \leq s \leq t$. Hence, relations between such monomials corresponding to difference conditions for $W(Λ^{(r)})$ automatically become relations in $L(Λ)$ (cf. [3]). This gives the following family of relations on $L(Λ)$:

$$
\sum_{i_1, \ldots, i_k, j_1, \ldots, j_k = 1}^{m_1, \ldots, m_\ell} C_{ij} x_{i_1j_1} (-1)x_{i_2j_2} (-1) \cdots x_{i_kj_k} (-1) = 0,
$$

for some nonnegative integers $C_{ij}$, where the sum runs over all such partitions $i,j$ of a multiset $\{1^{m_1}, \ldots, \ell^{m_\ell}\}$, $m_1 + \cdots + m_\ell = 2(k^{(r)} + 1)$.

Alternatively, for $r \geq 2$ let $\theta_{(r)} \subset \mathfrak{g}_0$ be the subalgebra generated by elements $x_{\pm \alpha_1}, 1 \leq t < r$. Start from a relation

$$
x_{11}(-1)^{k^{(r)}+1} (v^{(r)} \otimes v_{(r)}) = (x_{11}(-1)^{k^{(r)}+1} v^{(r)}) \otimes v_{(r)} = 0.
$$
PRESENTATIONS OF FEIGIN-STOYANOVSKY’S TYPE SUBSPACES

Now the adjoint action of $\mathbf{g}(r)$ on the above relation gives relations (3.3). For $r = 1$, relations (3.3) come down to only one relation

\[(3.5) \quad x_{11}(-1)^{k_0+1}(v^{(1)} \otimes v_{(1)}) = 0.\]

Recall that Feigin-Stoyanovsky’s type subspace $W(\Lambda)$ is

\[W(\Lambda) = U(\tilde{\mathbf{g}}^-) \cdot v_\Lambda.\]

Since $\tilde{\mathbf{g}}_1$ is commutative, universal enveloping algebra of $\tilde{\mathbf{g}}^-_1$ is isomorphic to a polynomial algebra $\mathbb{C}[\tilde{\Gamma}^-]$. Hence, there is a surjection

\[f_\Lambda : \mathbb{C}[\tilde{\Gamma}^-] \to W(\Lambda), \quad f : m \to m \cdot v_\Lambda.\]

We want to describe the kernel of this map, $\ker f_\Lambda \subset \mathbb{C}[\tilde{\Gamma}^-]$, so that

\[W(\Lambda) \simeq \mathbb{C}[\tilde{\Gamma}^-]/\ker f_\Lambda,\]

as vector spaces.

**Theorem 3.1.** Let $J_\Lambda \subset \mathbb{C}[\tilde{\Gamma}^-]$ be the ideal generated by the following sets

\[U(\mathbf{g}_0) \cdot \left(\sum_{n_1, \ldots, n_{k+1} \geq 1, n_1 + \cdots + n_{k+1} = N} x_{11}(-n_1) \cdots x_{11}(-n_{k+1})\right), \quad \text{for } N \geq k + 1,
\]

\[U(\mathbf{g}(r)) \cdot x_{11}(-1)^{k(r)+1}, \quad \text{for } r = 2, \ldots, \ell,
\]

\[x_{11}(-1)^{k_0+1}.\]

Then $\ker f_\Lambda = J_\Lambda$.

**Proof.** From (3.1), (3.4) and (3.5), see also (3.2) and (3.3), it follows that the generators of $J_\Lambda$ lie in the kernel of $f_\Lambda$. Hence $f_\Lambda$ can be factorized to a quotient map

\[\bar{f}_\Lambda : \mathbb{C}[\tilde{\Gamma}^-]/J_\Lambda \to W(\Lambda).\]

This map is clearly a surjection, since $f_\Lambda$ is a surjection.

We can imitate the proof for the spanning set for $W(\Lambda)$ (cf. Proposition 2 and 4 in [3]) to reduce the spanning set for $\mathbb{C}[\tilde{\Gamma}^-]/J_\Lambda$. Consider the generators of $J_\Lambda$ and identify the minimal monomial inside each one; their multiples can be excluded from the spanning set. Like in [3], we get

\[B = \{m | m \text{ satisfies DC and IC for } W(\Lambda)\}\]

as a spanning set of $\mathbb{C}[\tilde{\Gamma}^-]/J_\Lambda$.

To see that $\bar{f}_\Lambda$ is an injection, note that $\bar{f}_\Lambda$ maps $B$ bijectively onto

\[\{\mu v_\Lambda | \mu \text{ satisfies DC and IC for } W(\Lambda)\} \subset W(\Lambda),\]

which is a basis of $W(\Lambda)$. This means that $B$ is also linearly independent. Hence $\bar{f}_\Lambda$ maps a basis of $\mathbb{C}[\tilde{\Gamma}^-]/J_\Lambda$ onto a basis of $W(\Lambda)$ and therefore $\bar{f}_\Lambda$ is a bijection.
