Case of Unrecognised of Maxillary Adenoid Cystic Carcinoma

Slučaj neprepoznatog adenoidnoga cističnog karcinoma u gornjoj čeljusti

Abstract

Adenoid cystic carcinoma is a less commonly diagnosed cancer that may affect the major or minor salivary glands. We present a 70 year old male patient who was admitted to the Department of Oral Medicine, School of Dental Medicine in Zagreb, Croatia due to pain in the right maxilla. In this case we report a case of the patient with unilateral pain in the maxilla & eye which lead to the diagnosis of adenoid cystic cancer without any visible oral lesions.

Key words
Carcinoma, Adenoid Cystic; Salivary Gland Neoplasms; Unilateral Pain in the Maxilla & Eye

Introduction

Adenoid cystic carcinoma is a rare malignant tumor with an incidence rate of less than 1% of all head and neck malignancies (1). It constitutes approximately 29.6% of minor salivary gland tumors (2) and affects both males and females, without any sex predilection, and usually occurs after the fifth decade of life (3). The palate is the most common site of intra-oral lesions. In the major salivary glands, adenoid cystic carcinoma most commonly affects the parotid and submandibular glands, while palate is most frequently affected in the area of minor salivary glands, followed by the floor of the mouth, tongue and lip. In some cases it can present in the jaws as a primary intraosseous tumor (4). Characteristic signs of adenoid cystic carcinoma are slow growth pattern, tendency to local recurrences, postponed appearance of the distal metastases as well as neural invasion (5). The most important prognostic factors include tumor size, grade, stage, lymph node involvement, neural invasion and margin status (6). Diagnosis is based on clinical examination, histopathological analysis of a biopsy specimen and imaging techniques.

Uvod

Adenoidni cistični karcinom rijedak je zločudni tumor s incidencijom manjom od 1 % među svim tumorima glave i vrata (1). Čini otprilike 29,6 % tumora malih žlijezda slinovnica (2) i podjednako zahvaća muškarce i žene, bez spolne predilekcije te se uglavnom pojavljuje u dobi nakon pedeset godina (3). Unutar usne šupljine najčešće zahvaćeno mjesto jest nepce. U velikim žlijezdama slinovnicama adenoidni cistični karcinom najčešće zahvaća parotidne i submandibularne žlijezde, a na nepcu područje malih slinovnica praćeno dnom usne šupljine, jezikom i usnicom. U pojedinim slučajevima nastaje u čeljustima kao primarni intrakostani tumor (4). Karakteristični znakovi adenoidog cističnog karcinoma su spori rast, sklonost lokalnim recidivima, odgođena pojava udaljenih metastaza te neuralna invazija (5). Najvažniji prognostički čimbenici uključuju veličinu tumora, stupanj, stadij, zahvaćenost limfnih čvorova, neuralnu invaziju i status rubova (6). Dijagnoza se temelji na kliničkom pregledu, histopatološkoj analizi biopsijskog uzorka i slikovnim tehnikama.

In this report, we present a case of sharp unilateral pain in the maxilla & eye in whom diagnosis of adenoid cystic carcinoma was established albeit no visible oral lesions could be seen.

Case report

A 70 year old male patient was admitted to the Department of Oral Medicine, School of Dental Medicine in Zagreb, Croatia in April 2017 due to pain in the right maxilla. In March 2016, he went to an ear, nose and throat (ENT) specialist due to pain in the right maxilla and a CT scan of the paranasal sinuses was obtained. Speckled zones of bone demineralization of the distant part of the right side of the hard palate were found. Since no soft tissue pathology could be seen, the patient was sent to MRI examination of the head which he never did. Our clinical examination revealed a mild asymmetry of the hard palate, therefore a panoramic image was taken. It showed a mass on the right side of the maxilla and the cheek (Figure 1). Furthermore, the patient was admitted to the Emergency Ophthalmology Department due to pain in the right eye. The ophtalmologist treated the patient's glaucoma and recommended the use of ultrasound for diagnostic imaging of the eye, which the patient did not perform. Six months after the first examination at our Department, he was admitted again and tumorous thickening of the right maxilla could be noticed (Figure 2). He was immediately referred to a maxillofacial surgeon and a biopsy of palatal swelling was taken. A histopathological analysis revealed a tumor of a minor salivary gland, composed of both cribriform and tubular areas of atypical cuboidal epithelial cells with fossae of central necrosis within the cribriform areas. The final diagnosis was established. It was an adenoid cystic carcinoma (Figure 3).

The MSCT of the head, neck, and thorax examination was performed by standard recording techniques with 3D reconstructions. On the transitions between the head and the neck in the projection of the maxillary antrum to the right, and on the right half of the nasal cavity, a soft neoplastic heterogeneous contrast-absorbed process of about 48 mm in diameter was shown. Craniocaudal dimension of the lesion was about 70 mm with invasion into the right orbit and the middle skull to the anterior part of the cavernous sinus. A dorsal lesion went to the right half of the sphenoidal sinus (Figure 4). On both sides of the neck, in region II, more oval lymph nodes without pathology were found.

Due to the size of the lesion and structures compromised, the tumor was inoperable, therefore, the patient was treated by radiotherapy. Radiation dose was 70 Gy divided at 35 fractions. After radiotherapy, the tumor has greatly reduced its size (Figure 5).

Discussion

The differential diagnosis of aggressive intraoral lesions should, among others, consider various salivary gland tumors. In case of an aggressive lesion which involves hard palate, differential diagnoses should involve adenoid cystic carcinoma of the minor salivary glands (2). Adenoid cystic

U ovom prikazu predstavljamo slučaj bolesnika s jednostranom oštrom boli u gornjoj čeljusti i oku kojem je postavljena dijagnoza adenoidnog cističnog karcinoma, a bez promjena u usnoj šupljini.

Prikaz slučaja

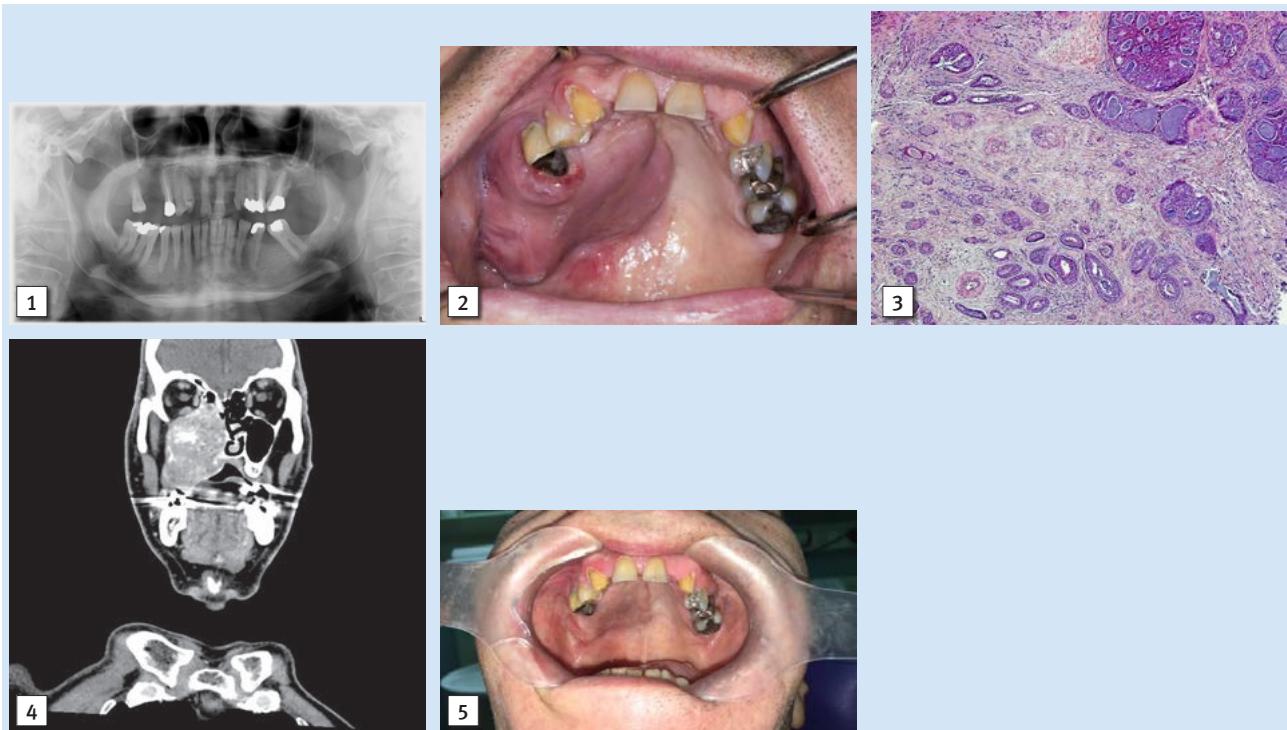

U Zavod za oralnu medicinu Stomatološkog fakulteta Sveučilišta u Zagrebu (Hrvatska) u travnju 2017. godine došao je 70-godišnjak zbog bolova u desnoj strani gornje čeljusti. U ožujku 2016. pregledao ga je otorinolaringolog zbog bolova s desne strane gornje čeljusti te je učinjen CT paranasalnih sinusa. U distalnom dijelu desne strane tvrdog nepca uočene su mrljaste zone demineralizacije kosti. S obzirom na to da na nalazu CT-a nije bilo vidljive patologije mekog tkiva, bolesnik je upućen na snimanje magnetskom rezonancijom koje nikad nije učinio. Naš klinički pregled otkrio je blagu asimetriju tvrdog nepca te je učinjen ortopantomogram (OPG). Na OPG-u bila je vidljiva masa na desnoj strani gornje čeljusti i obraza (slika 1.). Nadalje, bolesnik je hitno upućen na oftalmološki odjel zbog boli u desnom oku. Oftalmolog je liječio bolesnikov glaukom i preporučio ultrazvuk oka koji bolesnik nikad nije učinio. Šest mjeseci nakon prvog pregleda u našem zavodu, bolesnik je ponovno upućen te se učilo tumorsko zadebljanje desne strane gornje čeljusti (slika 2.). Odmah je poslan maksilofacialnom kirurgu te je učinjena biopsija otekline na gornjoj čeljusti. Histopatološka analiza pokazala je tumor malih žljezda slinovnica sastavljen od kribriformnih i tubularnih područja atipičnih kuboidalnih epitelnih stanica s jamicama središnje nekroze unutar kribriformnih područja. Postavljena je konačna dijagnoza – adenoid cističnog karcinoma (slika 3.).

Učinjen je MSCT glave, vrata i toraksa standardnim tehnikama snimanja s 3D rekonstrukcijom. Na presjecima glave i vrata u projekciji antruma maksile desno, te desne polovine nosne šupljine, vidljiv je mekotkivni neoplastični heterogeno kontrastno imbibiran proces od oko 48 mm u promjeru. Kraniokaudalna veličina lezije bila je otprilike 70 mm, s invazijom u desnu orbitu i srednju lubanjsku jamu do prednjeg dijela kavernoznog sinusa. Dorzalno se lezija pruža do desne polovine sfenoidnog sinusa (slika 4.). Na obje strane vrata u regiji II vidljivo je više ovalnih limfnih čvorova bez patoloških procesa.

Posljedično veličini lezije i kompromitiranim strukturama, tumor je bio inoperabilan te je bolesnik liječen zračenjem. Doza zračenja iznosila je 70 Gy i bila je raspodijeljena u 35 frakcija. Nakon liječenja zračenjem tumor se značajno smanjio (slika 5.).

Rasprrava

Diferencijalna dijagnoza agresivnih intraoralnih lezija, između ostalog, uključuje različite tumore žljezda slinovnica. Ako agresivna lezija obuhvaća tvrdo nepce, diferencijalna dijagnoza mora uključivati adenoidni cistični karcinom malih žljezda slinovnica (2). Ta novotvorina sporo i podmuklo ra-

carcinoma has a slow and often insidious growth pattern and most patients present at advanced stages of the disease. Based on tumor location, patients might have different signs and symptoms. Pain is a common clinical finding due to an early perineural invasion of the neoplastic cells (7). Adenoid cystic carcinoma develops frequently in minor salivary glands in comparison to the sublingual and parotid glands. Sometimes it starts as a jaw lesion (2).

It is a well known fact that the pain arising from non-dental causes might be confused as pain arising from the tooth, which leads to misdiagnosis. Park *et al.*, reported an adenoid cystic carcinoma of maxillary sinus misdiagnosed as chronic apical periodontitis (8). Therefore, pain associated to salivary gland malignant tumor may be misdiagnosed as pain from odontogenic origin.

In a recent study of 4004 periapical lesions which were diagnosed as endodontically associated pathoses, nine were found to be malignant processes, seven of which were squamous cell carcinoma, one Langerhans cell histiocytosis and one adenoid cystic carcinoma located in the mandible (9).

Perineural spread of the head and neck cancer was studied in a recent review (10). The results have shown that different types of head and neck tumors, including adenoid cystic

carcinoma has a slow and often insidious growth pattern and most patients present at advanced stages of the disease. Based on tumor location, patients might have different signs and symptoms. Pain is a common clinical finding due to an early perineural invasion of the neoplastic cells (7). Adenoid cystic carcinoma develops frequently in minor salivary glands in comparison to the sublingual and parotid glands. Sometimes it starts as a jaw lesion (2).

It is a well known fact that the pain arising from non-dental causes might be confused as pain arising from the tooth, which leads to misdiagnosis. Park *et al.*, reported an adenoid cystic carcinoma of maxillary sinus misdiagnosed as chronic apical periodontitis (8). Therefore, pain associated to salivary gland malignant tumor may be misdiagnosed as pain from odontogenic origin.

In a recent study of 4004 periapical lesions which were diagnosed as endodontically associated pathoses, nine were found to be malignant processes, seven of which were squamous cell carcinoma, one Langerhans cell histiocytosis and one adenoid cystic carcinoma located in the mandible (9).

Perineural spread of the head and neck cancer was studied in a recent review (10). The results have shown that different types of head and neck tumors, including adenoid cystic

carcinoma, can result in complications involving the afferent or efferent visual system. The authors have also reported involvement of trigeminal nerve and atypical facial pain. According to these data, a strong correlation between adenoid cystic carcinoma and pain in the ophtalmic region, as was shown in our patient, could be implicated.

The patient was treated only with radiotherapy. This case report highlights the fact that although the oral cavity finding might be without any visible lesions, sharp unilateral pain might suggest underlying malignancy in the affected area as it was seen in this case.

Sažetak

Adenoidni cistični karcinom rijed je dijagnosticirani tumor koji može zahvatiti velike i male žljezde slinovnice. Prikazan je slučaj 70-godišnjeg bolesnika koji je upućen u Zavod za oralnu medicinu Stomatološkog fakulteta u Zagrebu zbog boli u desnoj strani gornje čeljusti. U ovom slučaju opisujemo kako jednostrana oštra bol u gornjoj čeljusti i oku može ukazivati na dijagnozu adenoidnog cističnog karcinoma, iako bolesnik nema u usnoj šupljini vidljivih promjena.
