Beran, L.: Aquatic molluscs of the Mrežnica River. Nat. Croat. Vol. 28, No. 1., 99-106, Zagreb, 2019.

Results of a malacological survey of the Mrežnica River are presented. The molluscan assemblages of this river between the boundary of the Eugen Kvarternik military area and the inflow to the Korana River near Karlovac were studied from 2013 to 2018. Altogether 29 aquatic molluscs (19 gastropods, 10 bivalves) were found at 9 sites. *Theodoxus danubialis*, *Esperiana esperi*, *Microcolpia daudebartii* and *Holandriana holandrii* were dominant at most of the sites. The molluscan assemblages were very similar to assemblages documented during previous research into the Korana River. The populations of the endangered bivalves *Unio crassus* and *Pseudanodonta complanata* were recorded. An extensive population of another endangered gastropod *Anisus vorticulus* was found at one site. *Physa acuta* is the only non-native species confirmed in the Mrežnica River.

Key words: Mollusca, *Unio crassus*, *Anisus vorticulus*, Mrežnica, faunistic, Croatia

Beran, L.: Vodeni mekušci rijeke Mrežnice. Nat. Croat. Vol. 28, No. 1., 99-106, Zagreb, 2019.

U radu su predstavljeni rezultati malakološkog istraživanja rijeke Mrežnice. Sastav mekušaca ove rijeke proučavan je na području od Vojnog poligona Eugen Kvarternik do njenog utoka u Koranu blizu Karlovca, u razdoblju 2013. – 2018. ukupno je pronađeno 29 vrsta vodenih mekušaca (19 puževa, 10 školjkaša). Na većini lokaliteta dominirali su *Theodoxus danubialis*, *Esperiana esperi*, *Microcolpia daudebartii* i *Holandriana holandrii*. Sastav vrsta bio je vrlo sličan onom utvrđenom u prethodnom istraživanju rijeke Korane. Zabilježene su populacije ugroženih školjkaša *Unio crassus* i *Pseudanodonta complanata*. Na jednom od lokaliteta pronađena je veća populacija ugroženog puža *Anisus vorticulus*. Od alohtonih vrsta u ovom istraživanju rijeke Mrežnice potvrđena je jedino *Physa acuta*.

Ključne riječi: Mollusca, *Unio crassus*, *Anisus vorticulus*, Mrežnica, fauna, Hrvatska

INTRODUCTION

The Mrežnica River is the biggest tributary of the Korana River, situated in central Croatia, and belongs to the Danube River basin (Black Sea catchment area). In many karstic running waters of the Dinarid mountains freshwater molluscs are one of dominant macrobenthic groups and have an important role in the ecosystem of these rivers. Nevertheless, the aquatic molluscs of this river have not been investigated, while the freshwater molluscs of the Korana River were studied by the same author from 2009 to 2012 (BERAN, 2013). This research was continued with the survey of the Mrežnica River the results of which are presented here.

MATERIAL AND METHODS

Data were obtained from field surveys conducted in the years 2013-2018. In total, 9 sites were studied (Fig. 1). The main sampling method for aquatic molluscs applied also for this research is washing vegetation or sediments using a metal sieve (diameter 20 cm, 0.8 mm mesh) combined with collection by hand, the surfaces of stones, wood and artificial materials (e.g. plastic bags and bottles) being examined. Diving (snorkelling) in shallow parts (ca to 3 m deep) was also used. Freshwater molluscs were determined using shell characteristics or dissected and then identified using their copulatory organs if identification based on shells alone was impossible. Specimens for dissection were killed in hot water and then fixed in 80% ethanol. Selected material of shells and killed specimens in 80% ethanol are deposited in the author's collection.

Fig. 1. The map of the Mrežnica River with the sites under study. Drawn by H. Medková.

Study area

The Mrežnica River is located in central Croatia. The river has a total length of 63 km and a watershed area of 64 km². This river rises in Kordun, west of Slunj, and flows northwards, in parallel to the Korana, into which it flows near Karlovac. The river belongs to the Danube river basin. Like the Korana this river has a natural character at the most of its course. The Mrežnica is frequently overgrown with aquatic macrophytes and the river flow is interrupted with many waterfalls. The Tounjčica River is the biggest tributary of the Mrežnica.

List of investigated sites

Data in the list are as follows: site number, geographical co-ordinates, name of the nearest settlement, description of the site, date of investigation. Sites are depicted in Fig. 1.

1 – 45°27'56.5"N, 15°33'54.2"E, Karlovac, the Mrežnica River at inflow to the Korana River, 17.8.2013;

2 – 45°27'50.4"N, 15°32'27.8"E, Logorište, the Mrežnica River ca 2.5 km upstream of its confluence with the Korana River, 5.7.2014;

RESULTS

In total, 29 aquatic molluscs (19 gastropods, 10 bivalves) were found at 9 sites of the Mrežnica River between the boundary of the Eugen Kvarternik military area and the confluence with the Korana River near Karlovac. A list of molluscs found at particular sites and an estimation of the density of their populations are shown in Tab.1. *Theodoxus danubialis*, *Esperiana esperi*, *Microcolpia daudebartii*, *Holandriana holandrii* were dominant at most sites and their numerous populations constituted the dominant component of molluscan biomass. Also *Unio crassus*, *Pisidium amnicum* and *P. subtruncatum* were recorded at most of the sites. *Bithynia tentaculata*, *Lithoglyphus naticoides*, *Valvata piscinalis*, *Radix auricularia*, *Physa acuta*, *Unio pictorum*, *Anodonta anatina*, *Pisidium nitidum* were found at 5 or 6 studied sites. Other species were found at from 1 to 4 sites. Changes in the molluscan communities are visible up-stream. The species *Viviparus acerosus*, *Bithynia tentaculata*, *Valvata piscinalis*, *Pseudanodonta complanata* and *Pisidium henslowanum* are more typical for the lower and medium river sections while *Sadleriana fluminensis* was found only in the upper river section.

Populations of three endangered or rare species (one gastropod and two bivalves) were found. *Unio crassus* was documented at all studied sites while *Pseudanodonta complanata* was recorded at 3 sites (site No. 2, 4 and 6). More numerous populations of *U. crassus* were found at sites No. 2 and 7. A few specimens were recorded at other sites, as with the case of *P. complanata*. An extensive population of the endangered gastropod *Anisus vorticulus* was found at the confluence of the Mrežnica and Tounjčica rivers (site No. 7).

Only one non-native mollusc was recorded; the North American *Physa acuta* occurs at 5 sites.

DISCUSSION

Rich molluscan assemblages inhabit the Mrežnica River except at the last two sites. As in the Korana River (BERAN, 2013) the species *Theodoxus danubialis*, *Esperia esperi*, *Microcolpia daudebartii*, *Holandriana holandrii* were dominant and their numerous populations constituted the dominant component of molluscan biomass. Molluscan assemblages of the two rivers are very similar. Altogether 32 species were found during research into the Korana River (BERAN, 2013) while the Mrežnica is inhabited by 29 species. A total of 26 species occurred in both rivers.

The occurrence of the endangered bivalve *U. crassus* which is declining in most European countries was confirmed and population seems to be more numerous than in the Korana River. The situation with the other endangered bivalve *P. complanata* is the same. This clam was found at three sites while in the Korana River its occurrence was confirmed only at Karlovac downstream of the confluence of the rivers (BERAN, 2013). While the existence of populations of *U. crassus* or *P. complanata* could be expected due to their occurrence in the Korana River the finding of an extensive population of *A. vorticulus* was surprising. An extinction or a decrease in its population density has been observed in most European countries (VAN DAMME, 2012) and this dramatic change led to the species being considered for inclusion in the EU Habitats Directive (COLLING & SCHRÖDER, 2006). The nearest known sites at which it occurs in Croatia are Benča Lake in Vrana Lake Nature Park (BERAN *et al.*, 2013) and more sites are known from Krka National Park (BERAN, 2009, 2016). Its occurrence in the Mrežnica and Tounjčica rivers is very surprising because this species inhabits mostly various smaller water bodies in floodplains (TERRIER *et al.*, 2006). On the other hand the species also occurs in lakes in the Krka National Park (BERAN, 2009, 2016) and the confluence of the Mrežnica and Tounjčica rivers upstream of the waterfalls has a similar character. This species was confirmed from one site only but its occurrence at other sites can not be excluded and more detailed study of its occurrence in the Mrežnica and Tounjčica rivers is needed.

Physa acuta is the only non-native species found in the Mrežnica River while in the Korana River three non-native species (*P. acuta*, *Ferrissia fragilis*, *Sinanodonta woodiana*) were confirmed. *P. acuta* is common and widespread in Croatia and its occurrence is not surprising.

ACKNOWLEDGEMENTS

I am obliged to Helena Medková for preparing the map. I also thank to two anonymous reviewers for helpful comments.

SUMMARY

Aquatic molluscs of the Mrežnica River

L. Beran

This paper presents results of a malacological survey of the Mrežnica, the biggest tributary of the Korana River. Mrežnica has a natural character at the most of its course. The river is frequently overgrown with aquatic macrophytes and the watercourse is interrupted with many waterfalls. Freshwater molluscs at 9 sites between the boundary of the Eugen Kvarternik military area and the inflow to the Korana River near Karlovac were studied from 2013 to 2018. Altogether 29 aquatic molluscs (19 gastropods, 10 bivalves) were found at 9 sites. *Theodoxus danubialis*, *Esperiana esperi*, *Microcolpia daudebartii* and *Holandriana holandrii* were dominant at most of the sites. The molluscan assemblages were very similar to the assemblages documented during previous research into the Korana River. Populations of three endangered or rare species (one gastropod and two bivalves) were found. *Unio crassus* was documented at all studied sites while *Pseudanodonta complanata* was recorded at 3 sites. An extensive population of the endangered gastropod *Anisus vorticulus* was found at the confluence of the Mrežnica and Tounjčica rivers. While the existence of populations of *U. crassus* and *P. complanata* could be expected due to their occurrence in the Korana River the finding of the extensive population of the rare gastropod *A. vorticulus* was surprising. Due to the occurrence of more numerous populations of three endangered molluscs the Mrežnica River looks to be more important than the Korana River of which it is a tributary. Only one non-native mollusc *Physa acuta* was confirmed there.
