A Fibrational Method of Indexed Coinductive Data Types

Decheng MIAO, Chaoyang WANG, Xinsheng LIU, Yonglin LIANG

Abstract: As a fundamental issue in type theory, indexed coinductive data types (ICDT, for short) is of crucial importance, which is essentially semantic computing problem in programming. Based on fibrational method, this paper analyses semantic behaviours of ICDT and describes their universal coinductive rules. We executed some works in semantic computing and program logic of ICDT including their math structures and categorical properties. Example analyses prove the effectiveness of the proposed fibrational method and its applicability in program languages. Our work is based on fibration; a general math setting that can compute semantics automatically rather than depend on particular computing environments and syntactic forms of ICDT.

Keywords: category; coinductive data types; computation; fibration; programming

1 INTRODUCTION

The coinductive data type [1] analyses the semantic behaviours of data types in program languages and type theory; it is a dual concept of inductive data types with coalgebra as its math support [2, 3]. It observes the dynamic behaviours of languages during program execution. Inductive and coinductive data types form a complementary solution to improve the abilities of syntax construction and the semantic computation of program languages. ICDT, one kind of coinductive data type, has more semantic computing power and is capable of dealing with more complex data structures in programming. ICDT is an important part of programming and type theory. Traditional methods of ICDT, including category theory and coalgebra, make type theory models in the local Cartesian closed category, which then gives rise to two consequences: one is that indexed coinductive data types and the relation categories which describe their semantics co-exist in the same category together; another is that functor and its lifting are identical. Thus, this has some limitations to analyse semantic behaviours and depict coinductive rules.

Fibrations are a recently emerging trend in computer science, especially in categorical methods; they have many applications, such as database system modelling [4, 5], software specifications [6], and programming [7, 8]. In a fibrational setting, depicting the semantic behaviours of ICDT is no longer restricted to functions or morphisms, but is generalized to objects in a total category. More importantly, ICDTs and relation categories do not coexist in the same category any longer, but the latter constructs functor which is lifted in corresponding total categories to represent its abstracted semantic computing and program logic of ICDT. Hermida and Jacobs performed a great deal of work in this field [9].

We used fibrations to discuss ICDT in our works, firstly taking it to be the object set in the base category and taking its semantic behaviours to be the object set in total category; next we established the responsible relations in program logic directly between the ICDT and its semantic behaviours using an equation and quotient functor; lastly, we constructed the ICDT corecursive operations to describe abstract coinductive rules with universality using selffunctor constructed in base category and their corresponding lifting equation-preserving in the total category.

Our primary works have researched the semantic behaviours of ICDT and its coinductive rules using fibrations. The rest of the structure of our paper is as follows. In Section 2, we study some current related works. In Section 3 we introduce some basic concepts, such as the bifibration and reindexed functor. In Section 4, we present a single-sorted indexed fibration on slice categories to analyse the semantic behaviour of single-sorted ICDT and abstractly depict its coinductive rule with universality. In Section 5, we extend a discrete indexed object to the indexed category, developing single-sorted indexed fibration to many-sorted indexed fibration, and analysing the semantic behaviours of many-sorted ICDT and abstractly depicting its coinductive rule with universality. Lastly, we summarize our conclusions and discuss future researching work.

2 RELATED WORKS

As a coinductive data type whose abilities of semantic computation are stronger, ICDT takes coalgebra as its math foundation, introducing tools such as terminality and bisimulation to type theory, which has particular advantages in analyzing and describing the dynamic semantic behaviors of programming. From the perspective of document retrieval, Hagino maybe is the first one who worked on relationship between inductive and coinductive data type systematically using the dialgebras structure in [10]; his work laid the research foundation of the coinductive data type. However, there exist certain deficiencies in the polymorphism type system, the relationship between syntax construction and dynamic behaviors, the applications of coinduction data types.

Scholars' joint efforts provided the impetus for the further development of coinductive data types. Nogueira studied the relationship between inductive and coinductive data types and their application in polymorphism programming using bialgebra in [11]. Authors in [12] further melted the inductive and coinductive data type by λ bialgebra and distributive laws, which explored the relationship between syntax construction and dynamic behaviors of data types. Poll et al. extended the works of Hagino based on sub-type and inheritance, and they obtained results on the connections of inductive and
coinductive data types using the dual properties of algebra and coalgebra [13]. Greiner et al. brought coinductive principles in program languages. They studied coinductive data types in programming [1, 14]. Authors in [15] described indexed coinduction by co-recursion. All of the above results solved the aforementioned questions to some extent. Meanwhile, in the field of applications of coinductive data types, Gimenez studied some applications by Coq, the formal theory proof tool in [16]. Vene researched coinductive data types in the functional program language Haskell [17]. Most of the above results applied the methods of category theory and coalgebra, and those based on fibrations only focused on certain respects, such as the logic reason of coinductive data types and the validations of coinductive rules. For example, Hermida demonstrated the coinductive rules of final coalgebra with quotient types in [9]. Subsequently, Ghani et al. broke through the limitations of polynomial functors in [9], and developed their work to generic functors. Recently, they also presented λi - fibration, constructed parameterized units of measure fibrations UoM, and proved basic propositions of [18]. Based on [9], [19] proved the soundness of bisimulation coinduction in a fibrational setting, and provided a new categorical method of weak bisimulation by changing parameters. Chen and Urbanput forward a categorical method of automata theory, applied partial order set to optimization to study some concepts of the theory of algebraic automata in [20]. Based on seminal work by Worrell in [21], Hasuo et al. discussed coinductive predicates and final sequences in a fibration in [22], they identified some categorical 'size restriction' axioms that guarantee stabilization of final sequences after ω steps.

The current studies focus largely on coinductive data types, and the research on ICDT is still in its preliminary stage. There are many interesting questions in the field of semantics and programming; for instance, analyzing semantics behaviors and representing coinductive rules, particularly the latter are almost produced automatically. Those automatically produced coinductive rules lack a stable mathematical basis and concise formal specification. Our work focuses on semantics behaviors and coinductive rules of ICDT through fibrations. Comparing with conventional methods such as coalgebra and categorical theory, this paper achieved the following: it analyzed semantic behaviors of ICDT succinctly using fibrations, it improved program languages processing and proving abilities for the semantic behaviors of ICDT, and it presented and described the coinductive rule with universality of ICDT. Meanwhile, all such works do not depend on specific computing environment, but they supply a sturdy mathematic basis as well as brief and unified description modes to semantics computing and logic of programming.

Using fibrational methods to study ICDT in formal languages extends and deepens the conventional ways of coinductive data types at categorical theory, especially after coalgebras emerged, combining dually some category notions, including the fibration and the opposite fibration, reindexed functor and opposite reindexed functor, presents powerful vitality for fibrations in researching ICDT. There are wide development prospects in computer science theory foundations and engineering practice. Moreover, using fibrational method to research ICDT in formal semantics is not purely math research, but from the perspective of soft theory, integrating fibration method to the up-to-date results of type theory, formal languages and monads, this collaborates with fundamental study systematically and deeply for certain ICDT kernel problems including category interpreting of key notions, semantics behaviors and formal rules.

3 FIBRATION AND OPFIBRATION

3.1 Fibration and Reindexed Functor

We assume readers have some categorical foundations, such as functor, adjunction, and natural transformation. Considering they have not presupposed the set theoretical models based on mathematical logic, some current basic math literature does not require all morphisms to be set when category is defined, but rather analyzing from the practical application perspective of computer science, we deem it is reasonable to confine all morphisms to a set. If all objects and morphisms can form two sets, respectively, in a category, the category is called a small category in [23]. The whole objects discussed in our works are in view of the concept of small category; readers can find other details for fibrations in [23-25]. For a category \( C \), let \( \text{Obj} \subset C \) to be the objects set, \( \text{Mor} \subset C \) to be the morphisms set.

**Definition 1.** Let \( P : T \to \mathbb{B} \) be a functor between two small categories \( T \) and \( \mathbb{B} \), \( f : C \to D \in \text{Mor} \mathbb{B} \) and \( P(Y) = D \). A morphism \( u : X \to Y \in \text{Mor} T \) is a Cartesian arrow of \( f \) and \( Y \), if the following three are satisfied: (1) \( P(u) = f \). (2) For \( \forall \in Z \to Y \in \text{Mor} T \), \( \forall \in P(Z) \to C \in \text{Mor} \mathbb{B} \), the diagram commutes, i.e. \( f \cdot h = P(v) \). (3) There exists a unique \( w : Z \to X \in \text{Mor} T \) such that \( u \cdot w = v \) and \( P(w) = h \).

For the Cartesian arrow \( u \) of \( f \) and \( Y \), we say \( u \) lies above \( f \); similarly, \( Y \) lies above \( D \). If \( u \) is a cone \[23\] in category \( T \), then by the uniqueness of the cones morphism \( w \), the Cartesian arrow \( u \) in Definition 1 is also a universal cone \( i \) \( T \), namely, the limit cone. Accordingly, the vertex \( X \) of universal cone \( u \) is the terminal object of \( u \) \[26\]. Then by the universal properties of universal cones, the Cartesian arrow \( u \) is an isomorphism. We denote \( f^*_T \) for the Cartesian arrow \( u \) of \( f \) and \( Y \) in Definition 1 for simplification.

**Definition 2.** Let \( P : T \to \mathbb{B} \) be a functor between two small categories \( T \) and \( \mathbb{B} \). If there exists a Cartesian arrow \( f^*_Y \) of \( f \) and \( Y \) for \( \forall X \in \text{Obj} T \) and \( f \in : C \to P(Y) \in \text{Mor} \mathbb{B} \), then we call \( P \) a fibration.

Using Definition 2, a fibration is a functor that ensures a large number of Cartesian arrows. For a fibration \( P : T \to \mathbb{B} \), \( \mathbb{B} \) is called base category, \( T \) total category of \( P \). For any object \( C \in \text{Obj} \mathbb{B} \), \( \exists X \in \text{Obj} T \) and \( k : C \to \text{Mor} T \), if satisfying \( P(X) = C \) and \( P(k) = \text{id}_C \), then the sub-category \( \mathcal{T}_C \) of \( T \) composed of \( X \) and \( k \) is called a fiber over \( C \) \[23\], and \( k \) is a vertical morphism. In fact, fiber \( \mathcal{T}_C \) is a full subcategory of the total category \( T \).

**Example 1.** Let \( \text{Set} \) be the set category, \( \forall X \in \text{Obj} \text{Set} \), a predicate over \( X \) is a two-tuples \( (X, P) \), \( P : X \to \text{Set} \). For \( \forall X \in X \), \( P(x) \) forms a set, which describes the semantic behaviors of \( x \), and \( X \) is called the domain of predicate \( X \),
There exists a unique \( \mathcal{P} \), maps a monomorphism \( f \rightarrow \cdots \rightarrow \mathcal{P} \) for the arrow category, domain \( \mathcal{P} \). We can construct a Cartesian arrow \( \mathcal{P} \), \( \rightarrow \mathcal{P} \) (\( \rightarrow \mathcal{P} \)). Let \( g: X \rightarrow Y \) be a morphism in the base category \( \mathcal{Set} \) on the predicate fibration \( \mathcal{P} \) in Example 1, \( \rightarrow \mathcal{Set} \). We write \( \mathcal{I} \) for the identify functor, then a Cartesian arrow \( \mathcal{P} \rightarrow \mathcal{P} \) of \( g \) and \( \rightarrow \mathcal{Set} \) on the predicate category \( \mathcal{P} \) is \( (g, \mathcal{I}(\mathcal{Set})): \mathcal{Q} \rightarrow \mathcal{I} \).

**Example 2.** Write \( \mathcal{B} \rightarrow \mathcal{B} \) for the arrow category, domain functor \( \mathcal{B} \rightarrow \mathcal{B} \) maps an object \( f: X \rightarrow Y \) in \( \mathcal{B} \rightarrow \mathcal{B} \) to object \( X \) in \( \mathcal{B} \). We call \( \mathcal{B} \) a domain fibration above \( \mathcal{B} \). Functor cod: \( \mathcal{B} \rightarrow \mathcal{B} \) maps an object \( f: X \rightarrow Y \) in \( \mathcal{B} \rightarrow \mathcal{B} \) to the object \( Y \) in \( \mathcal{B} \). If \( \mathcal{B} \) has pullbacks [23], then we call cod the codomain fibration.

For object \( f: X \rightarrow Y \) in fiber \( \mathcal{B} \rightarrow \mathcal{B} \) on \( y \), we have morphism in the base category: \( f': X' \rightarrow Y \) in \( \mathcal{B} \rightarrow \mathcal{B} \) to object \( X' \) in \( \mathcal{B} \). We call \( \mathcal{B} \) a domain fibration above \( \mathcal{B} \). Functor cod: \( \mathcal{B} \rightarrow \mathcal{B} \) maps an object \( f: X \rightarrow Y \) in \( \mathcal{B} \rightarrow \mathcal{B} \) to the object \( Y \) in \( \mathcal{B} \). If \( \mathcal{B} \) has pullbacks [23], then we call cod the codomain fibration.

**Example 3.** Let category \( \mathcal{B} \) have pullbacks, then Sub(\( \mathcal{B} \)) is a category constituted by the sub-objects of \( \mathcal{B} \), that is, objects of Sub(\( \mathcal{B} \)) are mono-morphism equivalence classes. For \( \{f \} : X \rightarrow 1 \in \text{Obj} \text{Sub} (\mathcal{B}) \) and another object \( \{g\} : 1 \rightarrow 0 \) to \( [g] \) is \( (I \rightarrow J) : \{f\} \rightarrow \{g\} \in \text{Mor Sub} (\mathcal{B}) \). We write \( \alpha: I \rightarrow J \), \( \beta: X \rightarrow Y \) and \( \gamma : Y \rightarrow 0 \), thus it satisfies diagram commuting, i.e., \( \alpha \cdot [f] = \beta \cdot [g] \cdot [\gamma] \). Sub-object fibration: \( \text{Sub} (\mathcal{B}) \rightarrow \mathcal{B} \), maps a mono-morphism equivalence class \( [f] \) to its codomain.

Write \( f^\ast (Y) \) for domain of Cartesian arrow \( f^\ast \), then \( f^\ast (Y) \) lies over \( C \); that is, \( Y \in \text{Obj} \mathcal{T}_o \), \( f^\ast (Y) \in \text{Obj} \mathcal{T}_o \). Therefore we have the definition of a reindexed functor.

**Definition 3.** If \( f: C \rightarrow D \) in the base category \( \mathcal{B} \) is extended to be a functor \( f^\ast: \mathcal{T}_o \rightarrow \mathcal{T}_o \) between fibers \( \mathcal{T}_o \) and \( \mathcal{T}_o \), then we call \( f^\ast \) a reindexed functor induced by \( f \).

Morphism \( f \) is the relationship between ICĐTs in the base category, and reindexed functor \( f^\ast \) is a lifting of \( f \) in the total category, which is related to their semantic behaviors.

### 3.2 Opfibration and Opposite Reindexed Functor

**Definition 4.** Let \( P: \mathcal{T} \rightarrow \mathcal{B} \) be a functor between two small categories \( \mathcal{T} \) and \( \mathcal{B} \); \( f: C \rightarrow D \in \text{Mor} \mathcal{B} \), \( w: X \rightarrow Y \in \text{Mor} \mathcal{T} \). The morphism \( u \) is called to be an opposite Cartesian arrow of \( f \) and \( X \) if three following holds: (1) \( P(u) = f \), (2) For \( \forall \mathcal{T} \in \text{Mor} \mathcal{B} \) and \( \forall h: D \rightarrow P(Z) \in \text{Mor} \mathcal{B} \), this satisfies diagram commuting, that is, \( h \cdot f = P(v) \). (3) There exists a unique \( w: X \rightarrow Z \in \text{Mor} \mathcal{T} \) such that \( w \cdot u = v \) and \( P(w) = h \).

Similar to Definition 1, if \( u \) is a cocone [23] in category \( \mathcal{T} \), then the opposite Cartesian arrow \( u \) in Definition 4 is a universal cocone in \( \mathcal{T} \) through the uniqueness of the cocones morphism \( w \), namely, the colimit cocone. Accordingly, the vertex \( Y \) of the universal cocone \( u \) is the initial object of \( u \) in [26], while the opposite Cartesian arrow \( u \) is an isomorphism by the universal properties of universal cocones.

**Definition 5.** Let \( P: \mathcal{T} \rightarrow \mathcal{B} \) be a functor between two small categories \( \mathcal{T} \) and \( \mathcal{B} \). If \( \forall X \in \text{Obj} \mathcal{T} \) and \( \forall P(Y) \in \text{Mor} \mathcal{B} \), there exists an opposite Cartesian arrow of \( f \) and \( X \), then we call \( P \) an opfibration.

**Definition 6.** If the functor \( P: \mathcal{T} \rightarrow \mathcal{B} \) between two small categories \( \mathcal{T} \) and \( \mathcal{B} \) is a fibration and an opfibration simultaneously, then it is a bifibration. Write \( f^\natural \mathcal{P} \) for the opposite Cartesian arrow \( u \) of \( f \) and \( X \) in Definition 4. Let \( f^\natural (X) \) be the codomain of \( f^\natural \). Then we say \( f^\natural (X) \) lies above \( D \), i.e., \( X \in \text{Obj} \mathcal{T} \), \( f^\natural (X) \in \text{Obj} \mathcal{T} \). We define \( f^\natural (X) \) as \( f^\natural (X) \rightarrow \mathcal{B} \rightarrow \mathcal{B} \) between fibers \( \mathcal{T}_c \) and \( \mathcal{T}_o \), then \( f^\natural (X) \) is an opposite reindexed functor induced by morphism \( f \).

### 3.3 Adjoint Properties of Reindexed and Opposite Reindexed Functor

**Definition 8.** If \( f: \mathcal{T} \rightarrow \mathcal{B} \) is a pair of adjoint functors, \( \eta, \varepsilon \) is the unit and counit, respectively, and for \( \forall X \in \text{Obj} \mathcal{C} \), \( \forall Y \in \text{Obj} \mathcal{B} \), \( \exists ! \phi: \mathcal{T} \rightarrow \mathcal{B} \) such that \( \phi \) is the transpose of \( f \) and \( g \) are \( G(f) \eta_X \) and \( \eta_Y () \), respectively.

**Theorem 1.** Let \( P: \mathcal{T} \rightarrow \mathcal{B} \) be a bifibration between the two small categories \( \mathcal{T} \) and \( \mathcal{B} \), then \( P \) is a bifibration iff \( \forall f: \mathcal{T} \rightarrow \mathcal{B} \), \( f^\natural \) has a left adjoint functor \( f^\ast \).
ensures the unique existence of \( f^* (\phi) \); it satisfies diagram commuting, that is, 
\[
\hat{\phi} l = \phi \circ f^* (\phi) \cdot \nu_X = f^* \circ \phi \cdot f^* (\phi) \cdot \nu_X = f^* \cdot \phi \cdot g = \hat{g}
\]
This proves the uniqueness of the morphism \( \phi \) in fiber \( \mathcal{C}_b \).

Then the transpose \( \hat{\phi} \) of \( \phi \) is the unique morphism from \( l \) to \( g \), and \( \hat{\phi} \) is also a morphism \( \phi \) to \( \nu_X \). Then by Definition 4, \( l \) is an opposite Cartesian arrow \( f^* \) above \( f \).

Remark 1. Theorem 1 gives a condition for determining if a functor is a bifibration. It also combines the adjoint property of the reindexed functor \( f^* \) and the opposite reindexed functor \( \hat{f} \) in the fibrational settings.

4 SEMANTIC BEHAVIOURS OF SINGLE-SORTED ICDT AND ITS CONDUCTIVE RULE

From the viewpoint of fibrations, single-sorted ICDT is an ICDT with discrete indexed objects, such as streams, lists, and trees. Based on the results from [27] and [28], this section constructs single-sorted indexed fibration by fibrations, analyzes semantic behaviors of single-sorted ICDT, and presents a coinductive rule of single-sorted ICDT with universality.

4.1 Semantic Behaviours of Single-Sorted ICDT

4.1.1 Truth Functor and Relation Fibration

Definition 9. Let \( \mathcal{C} \) be a fibration between two small categories \( \mathcal{T} \) and \( \mathcal{B} \). Let \( \forall \mathcal{T} \in \mathcal{B} \), if \( \exists \mathcal{T} \in \mathcal{B} \) is a terminal object in fiber \( \mathcal{T} \), and for \( \forall \mathcal{C} : \mathcal{T} \rightarrow \mathcal{B} \), \( f^* (\mathcal{I}) \) is a terminal object in fiber \( \mathcal{T}_c \), i.e., the reindexed functor \( f^* \) preserves terminal objects, then we state that fiber \( \mathcal{P} \) has fibered terminal objects.

The fibered terminal object of predicate fibration \( \mathcal{P} \) in Example 1 is a function map of all elements in the set \( X \) to a singleton set. The fibered terminal object of the codomain fibration \( \mathcal{C} \) in Example 2 is an identity functor. The sub-object fibration \( \mathcal{S} \) in Example 3 is an equivalence class of identity function.

Definition 10. Let \( \mathcal{C} \) be a fibration between two small categories \( \mathcal{T} \) and \( \mathcal{B} \), and the functor \( \mathcal{T} \rightarrow \mathcal{B} \) maps \( \forall \mathcal{C} \in \mathcal{B} \) to a terminal object in fiber \( \mathcal{T}_c \). Then \( \mathcal{T} \) is a truth functor of fibration \( \mathcal{P} \). If \( \mathcal{T} \) has one right adjoint functor \( \{ - \} \), then we call \( \{ - \} \) a comprehension functor of \( \mathcal{P} \).

Let \( \mathcal{I}_x \) and \( \mathcal{I}_y \) be the terminal objects of the base category \( \mathcal{B} \) and the total category \( \mathcal{T} \), respectively. Then \( \mathcal{T} \) is a truth functor of fibration \( \mathcal{P} \). For \( \mathcal{C} \in \mathcal{B} \), there exists a unique morphism \( \mathcal{C} : \mathcal{T} \rightarrow \mathcal{B} \) such that \( \mathcal{T} \rightarrow \mathcal{B} \), \( \mathcal{C} \rightarrow \mathcal{B} \), \( \forall \mathcal{C} \in \mathcal{B} \), \( \mathcal{T} \rightarrow \mathcal{B} \), we have \( f^* (\mathcal{T} \rightarrow \mathcal{B}) \rightarrow \mathcal{T} \rightarrow \mathcal{B} \), and the truth functor \( \mathcal{T} \rightarrow \mathcal{B} \) maps \( f^* \) to its Cartesian arrow \( f^* (\mathcal{I}_x) \) in total category \( \mathcal{T} \).

Definition 11. Let \( \mathcal{C} \) be a fibration between two small categories \( \mathcal{T} \) and \( \mathcal{B} \), its base category \( \mathcal{B} \) has products. Let \( \mathcal{T} \) be a diagonal endo-functor above \( \mathcal{B} \), which maps \( \forall \mathcal{C} \in \mathcal{B} \) to the product object \( \mathcal{C} \times \mathcal{C} \). Then the pullback of \( \mathcal{P} \) along \( \mathcal{A} \) forms fibration \( \mathcal{Rel}(\mathcal{P}) : \mathcal{Rel}(\mathcal{T}) \rightarrow \mathcal{B} \), \( \mathcal{Rel}(\mathcal{P}) \) is called to be a relation fibration of \( \mathcal{P} \).

The object of the total category \( \mathcal{Rel}(\mathcal{T}) \) on \( \mathcal{Rel}(\mathcal{P}) \) is relation \( \mathcal{C} \times \mathcal{D} \); for another object \( \mathcal{C} \), \( \mathcal{D} \), let \( \mathcal{f} : \mathcal{C} \rightarrow \mathcal{C} \) and \( \mathcal{g} : \mathcal{D} \rightarrow \mathcal{D} \) be two morphisms. Then \( \mathcal{f} \) and \( \mathcal{g} \) are morphisms \( \mathcal{C} \rightarrow \mathcal{C} \times \mathcal{D} \times \mathcal{D} \mathcal{A} \) in \( \mathcal{Rel}(\mathcal{T}) \). The relation fibration \( \mathcal{Rel}(\mathcal{P}) \) in Fig. 3 maps the relation \( \mathcal{C} \times \mathcal{D} \) to object \( \mathcal{C} \in \mathcal{B} \); functor \( \mathcal{T} \) maps \( \mathcal{C} \rightarrow \mathcal{B} \), and \( \mathcal{D} \rightarrow \mathcal{B} \) is \( \Delta(\mathcal{C}) \). Moreover, the property pullback-preserving of Definition 11 ensures that fiber \( \mathcal{Rel}(\mathcal{T}) \) above \( \mathcal{C} \) on \( \mathcal{Rel}(\mathcal{P}) \) is an isomorphism to fiber \( \mathcal{C} \times \mathcal{C} \times \mathcal{C} \times \mathcal{C} \), i.e., \( \mathcal{Rel}(\mathcal{T}) \times \mathcal{Rel}(\mathcal{P}) \) is the pullback of \( \mathcal{C} \times \mathcal{C} \times \mathcal{C} \times \mathcal{C} \).
The procedure of building new fibration using specific fibration is called to be change of base. For instance, we can build \( \text{Rel}(P) \) using the change of base from \( P \) in Definition 11. The change of base keeps construction including preserving fibered terminal objects in \([26]\); if the fibration \( P \) has one truth functor \( T_P \), then its relation fibration \( \text{Rel}(P) \) has truth functor \( T_{\text{Rel}(P)} \). Meanwhile, we can gain \( T_{\text{Rel}(P)}(C) = T_P(C \times C) \). The predicate fibration \( \text{Pre} \) in Example 1 constructs a relation fibration \( \text{Rel}(\text{Pre}) \) using a change of base, and its truth function maps set \( X \) to a two-tuple relation \( R:X \times X \rightarrow \mathit{Set} \), i.e., it maps each ordered pair \((x, x')\) to a singleton set \( \{x'\} \).

**Theorem 2.** Let \( P : \mathbb{X} \rightarrow \mathbb{B} \) be a bifibration between two small categories \( \mathbb{X} \) and \( \mathbb{B} \); base category \( \mathbb{B} \) has pullbacks. If for each pullback square in \( \mathbb{B} \), natural transformation \( \ast \rightarrow \cdot : \mathbb{B} \rightarrow \mathbb{B} \) is an isomorphism, then \( P \) satisfies Beck-Chevalley condition.

**Proof.** Let \( \eta \) be the unit of the adjoint functor \( \ast \rightarrow \cdot \) , and let \( e_i \) be the counit of the adjoint functor \( \ast \leftarrow \cdot \) (Fig. 4). Then \( \eta = \text{Id}_{T_P} \), \( e_i = \text{Id}_{T_P(C)} \). The following equation holds:

\[
(s \cdot t) \ast (f \cdot g) = \eta(f \cdot g) \ast \eta(f) \cdot \eta(g).
\]

Then the single-sorted indexed functor \( \mathbb{B} \rightarrow \mathbb{B} \) also maps \( \mathbb{B} \rightarrow \mathbb{B} \).

**Remark 2.** In other word, based on the pullback square in the base category on a bifibration, Theorem 2 defines a natural transformation whose functors preserve the structure between corresponding fibers in the total category \( \mathbb{T} \). The theorem further ensures the reindexed functor and the opposite reindexed functor satisfy appropriate properties of diagram commuting. For example, the predicate fibration \( \text{Pre} \) in Example 1 and the codomain fibration \( \text{cod} \) in Example 2 both satisfy the Beck-Chevalley condition in Theorem 2.

**Definition 12.** Let \( P : \mathbb{T} \rightarrow \mathbb{B} \) be a bifibration which is satisfying the Beck-Chevalley condition; the base category \( \mathbb{B} \) has products, furthermore, \( T_P \) is one truth functor of \( P \). For any \( \forall C \in \text{Obj} \mathbb{B} \) the active function \( \delta_C : C \rightarrow C \times C \) of natural transformations \( \delta : \text{Id}_C \rightarrow \Delta \rightarrow \mathbb{C} \) on \( C \) extend one opposite reindexed functor \( \ast \rightarrow \cdot \). Meanwhile, \( \text{Eq}_P : \mathbb{B} \rightarrow \text{Rel}(\mathbb{T}) \) is one equation functor of \( P \), we can obtain \( \text{Eq}_P = \delta \cdot T_P \).

The truth functor \( T_P \) of \( T \) is mapping \( C \) to one terminate object \( T_P(C) \) in fiber \( T_P(C) \). From Definition 11, we can obtain that \( \text{Rel}(P) \) is the change of base of \( P \) along \( \Delta \). So if fibration \( P \) has one fibered terminate object, then its relation fibration \( \text{Rel}(P) \) has one fibered terminate object too. If the opposite reindexed functor \( \ast \rightarrow \cdot \) can map terminate object \( T_P(C) \) to the \( \ast \rightarrow \cdot (T_P(C)) \), then \( \text{Eq}_P \) of \( P \) also map \( \forall f \in \text{Mor} \mathbb{B} \) to only one unique morphism on \( f \times f \) which is determined by \( \delta \) and \( (\delta_C)^{-1} \).

The intuitive implication of the equation functors is that identical parameters have identical results \([9]\). Take the predicate fibration \( \text{Pre} \) in Example 1 as an example; the object in its fiber \( \text{Rel}(\mathbb{T})_C \) is the equation relation \( R : \mathbb{X} \times \mathbb{X} \rightarrow \mathit{Set} \), and \( \text{Eq}_{\text{Pre}}(C)(x, x') = 1 \) if \( x \neq x' \); and \( \text{Eq}_{\text{Pre}}(C)(x, x') = 0 \) if otherwise.

### 4.1.2 Single-Sorted Indexed Fibration and its Equation Functor

**Theorem 3.** Let \( P : \mathbb{T} \rightarrow \mathbb{B} \) be a bifibration or fibration between two small categories \( \mathbb{T} \) and \( \mathbb{B} \). Then \( T_P : \mathbb{B} \rightarrow \mathbb{T} \) is one truth functor for \( P \). So, \( \exists ! \in \text{Obj} \mathbb{B} \), \( I \) is one discrete indexed target on the base category \( \mathbb{B} \). Assume the single-sorted indexed functor \( P / I : \mathbb{T} \rightarrow \mathbb{B} \) to be \( P / I(u) = \text{Obj} \mathbb{B} / I \) for \( \forall u : Y \rightarrow T_P(I) \rightarrow \text{Obj} \mathbb{B} / I \) (Fig. 5). Then the single-sorted indexed functor \( P / I \) is also a fibration or bifibration.

**Proof.** For \( \forall f : C \rightarrow D \in \text{Mor} \mathbb{B} \), we can get one Cartesian arrow \( f' : f(X) \rightarrow X \) on \( f \) about fibration \( P \), which satisfies \( P(X) = D \). We also obtain an only morphism \( w : T_P(I) \rightarrow f'(X) \) so have \( v = f' \cdot w \) and \( P(v) = f \cdot h \) (Fig. 5). On the supposition that we have \( \alpha : D \rightarrow I \in \text{Obj} \mathbb{B} / I \), \( \beta : C \rightarrow I \in \text{Obj} \mathbb{B} / I \). So \( \gamma : P(v) \rightarrow D = \text{Obj} \mathbb{B} / I \), \( \delta : P(v) \rightarrow I \in \text{Obj} \mathbb{B} / I \), and the diagram commutes: \( \gamma = f \cdot \delta \). In the total category \( \mathbb{T} / T_P(I) \) on functor \( P / I \), \( X : T_P(I) \in \text{Obj} \mathbb{B} / I \), \( f(X) : T_P(I) \in \text{Obj} \mathbb{B} / I \), we have \( g : u \rightarrow s = Y \rightarrow X \in \text{Mor} \mathbb{T} / T_P(I) \). Then we can obtain an only morphism, such that the diagram commutes, i.e.
By Definition 1, \( f_{z}^{j} \) is a Cartesian arrow of \( f \) on functor \( P / I \). So if \( P \) is a fibration, then the single-sorted functor \( P / I \) is also a fibration.

Let \( m : Z \to T_{P}(l) \in \text{Obj}\, \Sigma / T / T_{P}(l) \). So \( P / I (m) = \alpha \) using functor \( P / I \). Meanwhile, assume \( f_{s}^{j} : Z \to \tau(z) \) one opposite cartesian arrow for \( f \) about \( P \) (Fig. 6). The commuting diagrams in the slice categories \( \mathbb{B} / l \), \( \alpha = \beta \cdot f \), and we can obtain one only morphism \( m'f(Z) \to T_{P}(l) \) in the total categories \( T / T_{P}(l) \) over functor \( P / I \) such that the diagrams commute, \( m = n \cdot f_{z}^{j} \). By Definition 4, \( f_{z}^{j} \) is an opposite Cartesian arrow of \( f \) on functor \( P / I \). Namely, if \( P \) is an opposite fibration, then the single-sorted indexed functor \( P / I \) is also an opposite fibration.

Therefore, if \( P \) is a fibration or bifibration, then the single-sorted indexed functor \( P / I \) is also a fibration or bifibration.

**Remark 3.** Theorem 3 proves that the single-sorted indexed fibration \( P / I \) and fibration \( P \) have the same properties of fibration or bifibration; we also provide the definition of a single-sorted indexed fibration. In fact, a change of base of \( P \) along the domain functor \( \text{dom} : \mathbb{B} / l \to \mathbb{B} \) in Example 2 can construct a single-sorted indexed fibration \( P / I, T / T_{P}(l) \to \mathbb{B} / l \). For \( \forall \alpha : C \to l \in \text{Obj}\, \mathbb{B} / l \), the fiber \( T_{C} \) above \( C \) on \( P \) is an isomorphism to the fiber \( (T / T(l))_{\alpha} \) above \( \alpha \) on \( P / I [28] \), and if \( P \) has a truth functor, then the single-sorted indexed fibration \( P / I \) constructed by \( P \) also has a truth functor.

Any \( \forall \alpha : C \to l \in \text{Obj}\, \mathbb{B} / l \), we presume two pull-backs of \( \alpha \) along \( l \) to be \( i \) and \( j \), separately. So the productive object of \( \alpha \times \alpha \) is \( \alpha \cdot i \) or \( \alpha \cdot j \). Namely, the productive object \( \mathbb{B} / l \) in those slice categories is ascertainment by the pullback. Analogously, for definition 11, the subsequent result is the concept of a relation fibration of the single-sorted indexed fibration \( P / I \).

**Definition 13.** Assume \( P / I, T / T_{P}(l) \to \mathbb{B} / l \) to be a single-sorted indexed fibration. The base categories \( \mathbb{B} / l \) have product. Presume \( \Delta / l : \mathbb{B} / l \to \mathbb{B} / l \) to be one bidualagonal selffunctor in the sliced category \( \mathbb{B} / l \). So \( \Delta / l \) mapping \( \forall \alpha \in \mathbb{B} / l \) to the product object \( \alpha \times \alpha \). Then pullbacks of \( P / I \) along \( \Delta / l \) makes one fibration \( \text{Rel}(P / I) \in \text{Rel}(T / T_{P}(l)) \to \mathbb{B} / l \). At the same time, \( \text{Rel}(P / I) \) is one relation fibration for \( P / I \).

For an object \( R \in \text{Obj}\, \Sigma / T / T_{P}(l) \) above \( \alpha \) on \( \text{Rel}(P / I) \), an object \( R' \in \text{Obj}\, \Sigma / T / T_{P}(l) \) above \( \alpha \times \alpha \) on \( P / I \) and an object \( R'' \in \text{Obj}\, \Sigma / T_{P}(l) \) above \( \text{dom}(\alpha \times \alpha) \) on \( P \), there exists the isomorphism \( R \cong R' \cong R'' \) in [28]. The action function of \( \alpha \) on the natural transformation \( \delta / l : \text{Id}_{\mathbb{B} / l} \to \Delta / l \) is \( (\delta / l)_{\alpha} : C \to \text{dom}(\alpha \times \alpha) \). Then the intuitional meaning of the natural transformation \( \delta / l \) is a morphism from one object to another object in the slice category \( \mathbb{B} / l \). Similarly, for Definition 12, the following defines the equation functor of a single-sorted indexed fibration \( P / I \).

**Definition 14.** Let \( P : T \to \mathbb{B} \) be a bifibration satisfying Beck-Chevalley condition between two small categories \( \mathbb{T} \) and \( \mathbb{B} \), where \( P \) has the truth functor, and base category \( \mathbb{B} \) has the product. Let the truth functor of a single-sorted index fibrations \( P / I \) be \( T_{P} \). So \( E_{\text{Eq}(P / I)} = (\delta / l)_{\alpha} \cdot T_{P}(l) : \mathbb{B} / l \to \text{Rel}(T / T_{P}(l)) \) is called to be one equation functor for \( P / I \).

The equation functor \( E_{\text{Eq}(P / I)} \) maps the object \( \alpha : C \to l \) in the slice category \( \mathbb{B} / l \) to a unique morphism \( (\delta / l)_{\alpha} \cdot T_{P}(l) \) above \( \alpha \times \alpha \). The following constructs the quotient functor using the single-sorted indexed fibration \( P / I \).

### 4.1.3 Quotient Functor and its Lifting

Let truth functor \( T_{P} : \mathbb{B} \to \mathbb{T} \) of fibration \( P : \mathbb{T} \to \mathbb{B} \) be substituted with the equation functor \( E_{\text{Eq}(P / I)} \). Next, applying Theorem 3, we make another fibration, i.e., \( \text{Rel}(P / I) \in \text{Rel}(P / I) \) on \( P / I \). Assume adjoint functors \( E_{\text{Eq}(P / I)} \) such that \( E_{\text{Eq}(P / I)} = (\delta / l)_{\alpha} \cdot T_{P}(l) \). Then \( \text{Rel}(P / I) \) and \( \text{Rel}(P / I) \) is called to be the quotient functor of the single-sorted indexed fibration \( P / I \). We write \( \text{Rel}(P / I) \) to \( E_{\text{Eq}(P / I)} \) and \( \text{Rel}(P / I) \) to \( \text{Eq}(P / I) \).
\( f : D \rightarrow T_p(l) \in \mathbb{Ob}\mathcal{T} / T_p(l) \) \; ; \; \text{we have} \; P / I(f) = P(D) \rightarrow I \; ,

and there exists an object \( g: C \rightarrow I \in \mathbb{Ob}\mathcal{B} / I \; ,

\( \Delta / I(g) = g \times g \) \; ; \; \text{therefore:} \; \text{dom}(g \times g) = P(D) \).

**Definition 16.** Let \( P : \mathcal{T} \rightarrow \mathcal{B} \) be one bi-fibration satisfies Beck-Chevalley requirement with a truth functor \( T_p \) among small category \( \mathcal{T} \) and \( \mathcal{B} \). Base categories \( \mathcal{B} \) have product and pullback. The back functor \( P / I : \mathcal{T} / T_p(l) \rightarrow \mathcal{B} / I \) is a single-sorted index fibration for \( P \; . \; \) We make a relational fibration \( \text{Rel}(P / I) \), an equational functors \( \text{Eq}_{P/1} \) with a quotient functor \( Q_{P/1} \) of \( P / I \; . \; \) Presume \( F \) to be one self functor into the base categories \( \mathcal{B} / I \) over \( \text{Rel}(P / I) \). Then \( F^+ \) is a self functor into the total categories \( \text{Rel}(\mathcal{T} / T_p(I)) \) over \( \text{Rel}(P / I) \). In case \( F^+ \) is satisfying commuted diagrams, i.e., \( \text{Rel}(P / I) \cdot F^+ = \text{Rel}(P / I) \; , \) some isomorphism expresses satisfy, \( \text{Eq}_{P/1} \cdot F \cong F^+ \cdot \text{Eq}_{P/1} \) and \( F \cdot Q_{P/1} \cong Q_{P/1} \cdot F^+ \). Then we call \( F^+ \) one lifting which is equation-preserving for \( F \) on \( \text{Rel}(P / I) \) into total category \( \text{Rel}(\mathcal{T} / T_p(I)) \).

### 4.1.4 Semantic Behaviours of Single-Sorted ICDT

Any \( \forall \alpha : C \rightarrow I \in \mathbb{Ob}\mathcal{B} / I \; , \) one \( F \) coalgebras \((a, r : \alpha \rightarrow F(\alpha))\) is made using action of selffunctor \( F \). We call \( \alpha \) the carrier of \( F \) coalgebras, the morphism between \((\alpha, r)\) and another \( F \) - coalgebra \((\beta, r : \beta \rightarrow F(\beta))\) is the morphism \( f : \alpha \rightarrow \beta \) between their carriers, which satisfies the diagram commutes; that is, \( f \cdot f = F(f) \cdot r \; . \) \( F \) - coalgebras category is composed of \( F \) - coalgebras and corresponding morphisms, writes \( \text{Coalg}_F \). If the terminal \( F \) - coalgebra \((vF, \text{out} : vF \rightarrow F(vF))\) exists, it is up to a unique isomorphism with the universal properties, which are determined by terminal coalgebra. The universal properties are our primary tool to research the semantic behaviors and coinductive rules of ICDT.

The single-sorted ICDT \( vF \), which is also the carrier of final \( F \) - coalgebras, is the max fixed points of the functor \( F \). The functor \( F \) is the syntax destructors of \( vF \). The corresponding morphism \( \text{out} \) describes a type of semantic behavior of \( vF \) during the syntax destruction externally. We apply equation functors \( \text{Eq}_{P/1} \) of the single-sorted indexed fibration \( P / I \; , \) it mapped \( F \) – coalgebra \((\alpha, r)\) to an \( F^+ \) - coalgebra, \( \text{Eq}_{P/1}(\alpha, r) = (\text{Eq}_{P/1}(\alpha), \text{Eq}_{P/1}(r)) : \text{Eq}_{P/1}(\alpha) \rightarrow \text{Eq}_{P/1}(F(\alpha)) \cong F^+ (\text{Eq}_{P/1}(\alpha)) \). Accordingly, \( \text{Eq}_{P/1}(vF) \) is the carrier of terminal \( F^+ \) - coalgebra. Therefore, the equation functor \( \text{Eq}_{P/1} \) preserves terminal objects.

Write \( \text{Coalg}(\text{Eq}_{P/1}) \) for the functor from \( \text{Coalg}_F \) to \( \text{Coalg}_{F^+} \), which maps all objects and their morphisms in the base category \( \mathcal{B} / I \) over relation fibration \( \text{Rel}(P / I) \) to ones into the total categories \( \text{Rel}(\mathcal{T} / T_p(I)) \) using the equation functor \( \text{Eq}_{P/1} \). Then the functor \( \text{Coalg}(\text{Eq}_{P/1}) \) establishes a relationship between \( \text{Coalg}_F \) and \( \text{Coalg}_{F^+} \).

If \( (\text{Eq}_{P/1}(vF), \text{out}^- : \text{Eq}_{P/1}(vF) \rightarrow F^+ (\text{Eq}_{P/1}(vF))) \) is a final \( F^+ \) - coalgebras into the total categories \( \text{Rel}(\mathcal{T} / T_p(I)) \) over relation fibration \( \text{Rel}(P / I) \) ; therefore, the \( \text{out}^- \) is one homomorphism image for \( \text{out} \) with the act of the corresponding functor \( \text{Coalg}(\text{Eq}_{P/1}) \), namely, we have \( \text{Coalg}(\text{Eq}_{P/1}(\text{out}^-)) = \text{out}^- \; . \) The final properties of final \( F^+ \) - coalgebras ensure \( \text{out}^- \) determines an only isomorphism, providing convenience in analyzing semantic behaviors accurately and exactly depicting the coinductive rule of single-sorted ICDT.

![Figure 8 Adjoint properties of Coalg(EqP) and Coalg(Qo)](image)

Similarly, write \( \text{Coalg}(\text{Eq}_{P/1}) \) for the functor from \( \text{Coalg}_{F^+} \) to \( \text{Coalg}_F \). Then we have \( \text{Coalg}(\text{Eq}_{P/1}) \) by the adjoint property of the adjoint functor \([9]\). For each \( F^+ \) - coalgebra \((\alpha, q : \alpha \rightarrow F^+ (\alpha))\), as \( X \rightarrow T_p(l) \in \mathbb{Ob}\mathcal{T} / T_p(I) \) ,

\[
\text{Coalg}(\text{Eq}_{P/1})(\alpha) = Q_{P/1} (\text{out}^-) \cong \text{Eq}_{P/1}(\alpha) \; . \]

Then we have \( \text{Coalg}(\text{Eq}_{P/1})(\alpha) = Q_{P/1}(\alpha) \; \). So \( Q_{P/1}(\alpha) \) be one of homomorphism images of \( q \) with the act of the functor \( \text{Coalg}(\text{Eq}_{P/1})(\alpha) \) (Fig. 8). If the morphism \( g : \alpha \rightarrow \text{Eq}_{P/1}(\alpha) \) is a \( F^+ \) - coalgebras morphism from \( q \) to \( \text{Eq}_{P/1}(\alpha) \), then the \( F^+ \) - coalgebras morphism \( h : \text{Eq}_{P/1}(\alpha) \rightarrow \alpha \) from \( \text{Eq}_{P/1}(\alpha) \), to \( r \) is an \( F \) - coalgebras homomorphisms about \( g \). Similarly, \( g \) is an \( F^+ \) - coalgebra homomorphism above \( h \).

The left adjoint \( \text{Coalg}(\text{Eq}_{P/1}) \) of functors \( \text{Coalg}(\text{Eq}_{P/1}) \) causes a presentative mutual deduction relations among \( F \) - coalgebras whose carrier is \( Q_{P/1}(\alpha) \), \( F^+ \) - coalgebras whose carriers are \( \alpha \), providing a concise and uniform model ways to the math specification of the coinductive rule of a single-sorted ICDT. The single-sorted ICDT \( vF \) is the carrier of terminal coalgebra, if functor \( \text{Coalg}(\text{Eq}_{P/1}) \) preserves terminal objects, then the lifting equation-preserving \( F^+ \) of \( F \) on \( \text{Rel}(P / I) \) generates a sound coinductive rule.

### 4.2 Coinductive Rule of Single-Sorted ICDT

One fibration equipped a quotient functor and equation functor, the math specifiction of coinductive rule is coherent to its semantics behaviors analysis of ICDT on this fibration \([9]\). If \( P : \mathcal{T} \rightarrow \mathcal{B} \) and \( P / I \; \). \( \mathcal{T} / T_p(l) \rightarrow \mathcal{B} / I \) content the conditions of Definition 16, and let \( F \) be a self functor into the base category \( \mathcal{B} / I \) over the relation fibration \( \text{Rel}(P / I) \) for \( P / I \) , let \( vF \) be one carrier of final \( F \)
- coalgebras, $F$ have its lifting which is equation-preserving $F^+$, then $P / I$ have the coinductive rules whose carrier is the single-sorted ICDT $vF$. This provides a sound basis of validity judgment for $F^+$ applying $F$ - coalgebra to generate a coinductive rule on a single-sorted ICDT. That is, the single-sorted index fibration $P / I$ equipping quotient functor and equation functor depicts semantics behaviors of the single-sorted ICDTs, their coinductive rules on account of final $F$ - coalgebras are available in the procedure of semantics behaviors description in program. Now we can obtain an universal coinductive rule which is provided abstractly into fibrational settings for a single-sorted ICDT.

On the basis of categoriatical theory, the corecursive computing of a coinductive data types rises in final coalgebras semantic [2]. Any $\forall \alpha : C \rightarrow I \in \mathbf{Obj} \mathbb{B} / I$, for $\forall F \in \mathbf{Obj} \mathbb{B} / I$, we use $F$ to make the corecursive manipulation $\text{unfold} : (\alpha \rightarrow F(\alpha)) \rightarrow \alpha \rightarrow vF$ to single-sorted ICDT into the base categories $\mathbb{B} / I$. An any $F$ -coalgebras $(a, r : a \rightarrow F(a))$, $\text{unfold} r$ is mapping $r$ to a sole $F$ -coalgebras morphism $\text{unfold} r : \alpha \rightarrow vF$, which is from $\alpha$ to the final $F$ -coalgebra $(vF, \text{out})$ (Fig. 9). Co-recursive manipulation $\text{unfold}$ origining in final coalgebras semantic is a corecursive parameterized manipulation of the ICDT in nature. The corecursive computing has many well-defined properties such as exact semantical description, adaptable expansibility and brief expressing.

![Figure 9](image)

In Definition 16, we have $E_{Q,F} (F(\alpha)) \simeq F^*(E_{Q,F}(\alpha))$, $E_{Q,F} (F(vF)) \simeq F^*(E_{Q,F}(vF))$, and the equation functor $E_{Q,F}$ preserves terminal objects. Clearly $E_{Q,F}(vF)$ is a carrier of final $F^+$ -coalgebras, writing it for $vF^+ = E_{Q,F}(vF)$, let $X = E_{Q,F}(\alpha)$. Using selffunctor $F^+$ makes the corecursive manipulation $\text{unfold} : (X \rightarrow F^+(X)) \rightarrow X \rightarrow vF^+$ for a single-sorted ICDT in the total categories $\text{Rel}(\mathbb{T} / T_p(I))$ (Fig. 10).

![Figure 10](image)

An $F^+$ - coalgebras $(X, q : X \rightarrow F^+(X))$, and $\text{unfold} q$ is mapping $q$ to a sole $F^+$ - coalgebras morphism $\text{unfold} q : X \rightarrow vF^+$ from $F^+$ - coalgebras $(X, q)$ to the final $F^+$ - coalgebras $(vF^+, \text{out}^+)$ . For $\forall \alpha \in \text{Obj} \mathbb{B} / I$, $\exists X \in \text{Obj} \text{Rel}(\mathbb{T} / T_p(I))$, we can obtain an universal coinductive rule for a single-sorted ICDT.

\[
\text{Coin}d_{\text{Uni}} : (X \rightarrow F^+(X)) \rightarrow X \rightarrow E_{Q,F}(vF) .
\]

If $(X, q : X \rightarrow F^+(X))$ is a $F^+$ -coalgebra over $F$ -coalgebras $(\alpha, r : \alpha \rightarrow F(\alpha))$, so $\text{Coin}d_{\text{Uni}}Xq$ is a $F^+$ -coalgebra homo-morphism on $\text{unfold} r$.

### 4.3 Instance Analysis of Single-Sorted ICDT

**Example 4.** The type of element of a stream or an infinite sequence is designated by index $I$, such as the natural number $\mathbb{Nat}$, integer $\mathbb{Int}$ and character $\mathbb{Char}$, $\forall I \in \mathbf{Obj} \mathbb{B}$. For any stream $\alpha : S \rightarrow I \in \mathbf{Obj} \mathbb{B} / I$, selffunctor $F : a \rightarrow I \times \alpha$ over $\mathbb{B} / I$, the operation head: $\alpha \rightarrow I$ is head function, another operation tail: $\alpha \rightarrow I$ is tail function after erasing the first item. Any streams properties $R \in \mathbf{Obj} \text{Rel}(\mathbb{T} / T_p(I))$ into the total categories $\text{Rel}(\mathbb{T} / T_p(I))$ over the relation fibration $\text{Rel}(P / I)$ for the single-sorted index fibration $P / I$, for instance, bisimulation. For the other stream object $\beta : S' \rightarrow I$ into $\mathbb{B} / I$, the coinduction for $\alpha$ and $\beta$ about bisimulation property $R$ is as follows: $R$ will be a relationship of bisimulation among two different streams, i.e., $\alpha$ and $\beta$ if and only if $\forall (\alpha, \beta) \in R$, for $(\text{tail}(\alpha), \text{tail}(\beta)) \in R$, there exists $\text{head}(\alpha) = \text{head}(\beta)$.

If stream data $\text{Stream}(I)$ is the carrier $vF$ of final $F$ -coalgebras $(vF, \text{out} : vF \rightarrow F(vF))$ into the base categories $\mathbb{B} / I$, then for every $F$ -coalgebras $(a, r : a \rightarrow F(\alpha))$, then it will be lifted to be a $F^+$ -coalgebras $(X, q : X \rightarrow F^+(X))$ using relation fibration $\text{Rel}(P / I)$, that is satisfying commutive diagrams, namely, $F \cdot \text{Rel}(P / I)(X) \simeq \text{Rel}(P / I) \cdot F^+(X)$. The terminal properties of final $F$ - coalgebras define a corecursive manipulation $\text{unfold} r$ about $\text{Stream}(I)$ that implements the determination for the single-sorted ICDTs $\text{Stream}(I)$. The other corecursive manipulation for terminality of final $F^+$ -coalgebras depicts the semantics behaviors for $\text{Stream}(I)$. If $q$ lies above $r$, then $\text{Coin}d_{\text{Uni}}Xq$ is a $F^+$ -coalgebra homomorphism on $\text{unfold} r$, and traversing every property $R$ into the total categories $\text{Rel}(\mathbb{T} / T_p(I))$ over corresponding relation fibration $\text{Rel}(P / I)$ for $\forall I \in \mathbf{Obj} \text{Rel}(\mathbb{T} / T_p(I))$, we can then have a semantics set $\{ R(X, X) \} \in \text{Eq}_{Q,F}(\alpha), \forall \alpha \in \mathbf{Obj} \mathbb{B} / I$ , that represents behavior of $\text{Stream}(I)$.

Taking Example 4 for an instance, $\text{unfold} r$ represents the map relation among stream $\alpha$ and its semantics behaviors vividly. The availability of $\text{unfold} r$ supplies an intuitive way to homo-morphism from coalgebras to final coalgebras, so we can establish the coinduction definition principle. To define function $\text{unfold} r : \alpha \rightarrow \text{Stream}(I)$, we only need to construct the corresponding operation $r$ on $\alpha$, and let $(\alpha, r)$ be an $F$ - coalgebra with $F(\alpha) = I \times \alpha$. Meanwhile, we can prove two homomorphisms are equivalent given the uniqueness of $\text{unfold} r$. So we have coinduction proof principle to demonstrate $m, n : \alpha \rightarrow \text{Stream}(I)$ is equivalent to each other, we just
demonstrate \( m \) and \( n \) are homomorphism from the identical co-algebras \((\alpha, r)\) to the final \( F - \) co-algebras \((\text{Stream}(I), \text{out} : \text{Stream}(I) \to F(\text{Stream}(I)))\) as well, \( m \) and \( n \) are also the same to unfold \( r \).

Example 4 presents some fibrational tools, including single-sorted indexed fibration, equation and quotient functor to analyze semantic behaviors deeply and coinductive rule of stream using fibrations, which establishes a mathematical foundation for researching semantic computing and the logic of program languages.

### 5 Semantic Behaviors and Coinductive Rule of Many-Sorted ICDT

Modeling based on the slice category \( \mathcal{B}/I \) analyzes semantic behaviors and describes the coinductive rule of single-sorted ICDTs indexed by \( I \). But \( I \) is only aimed at a single-sorted ICDTs, so hardly to process a more complicated many-sorted ICDTs effectively including reciprocal recursion types. On the basis of work ahead, we have extended the discrete indexed object \( I \) to an indexed category \( \mathcal{C} \), constructed a many-sorted indexed fibration, described a many-sorted ICDT in \( \mathcal{B} \) indexed by \( \text{obj} \mathcal{C} \), made a semantic behavior model of the many-sorted ICDTs in the indexed category \( \mathcal{C} \) based on fibration \( G : \mathcal{B} \to \mathcal{C} \) and chose different program logics for different indexes.

#### 5.1 Fibered Fibration

**Definition 17.** Let \( P : T \to \mathcal{B} \) and \( P' : T' \to \mathcal{B} \) be two fibrations between small categories. Also, let a fibered functor \( F : T \to T' \) from \( P \) to \( P' \) above the base category \( \mathcal{B} \) satisfy diagram commuting, \( P = P' \cdot F \). Then \( F \) preserves the Cartesian arrow.

**Definition 18.** Let \( F : T \to T' \) and \( G : T' \to \mathcal{B} \) be two fibered functors above the base category \( \mathcal{B} \). The fibered functor \( G \) is a right fibered adjoint functor to \( F \), and \( F \cdot G \) is a pair of fibered adjunction above \( \mathcal{B} \), if \( G \) is a right adjoint functor to \( F \), and the unit or counit of \( F \cdot G \) is vertical.

Definition 17 and Definition 18 lift standard category structures to fibered structures; it is easy to process many practical problems of many-sorted ICDTs with different discrete indexed objects in computer science. Using fibrational tools, such as truth and quotient functors in the base category, we can combine many-sorted ICDTs with their semantic behaviors. Applying reindexed and opposite reindexed functors between fibers in the total category in order to construct corecursive operations on many-sorted ICDTs to abstractly describe coinductive rules with universality. This does not depend on particular computing environments, but improves the cohesion of many-sorted ICDTs, and further enhances the independence of program languages.

Let \( P : T \to \mathcal{B} \) and \( G : \mathcal{B} \to \mathcal{C} \) be two fibrations between small categories. Given the composed property that composition of two fibrations is a fibration [23], \( GP \) is a fibration. For \( \forall a \in \text{obj} \mathcal{C} \), \( T_a \) is a fiber in the total category \( T \) on fibration \( GP \) over \( a \). The restriction \( P_a : T_a \to \mathcal{B} \) of \( P \) at \( a \) is a pullback of \( P \) along the including functor \( \text{Inc}: \mathcal{B} \to \mathcal{C} \), and \( E_a \) is a fiber in the total category \( \mathcal{B} \) on fibration \( G \) over \( a \). Then given the structure-preserving property of pullbacks [23], \( P_a \) is also a fibration.

Each \( P_a \) deals with different indexed object \( a \). Let \( P \) have a truth functor, so \( P_a \) also has a truth functor, denoted as \( T_a \). For a bifibration \( P \) that satisfies the Beck-Chevalley condition in Theorem 2, the right adjoint of the reindexed functor preserves terminal objects. When \( a \) iterates each indexed object in the indexed category \( \mathcal{C} \), a set of \( T_a \) constructs the truth functor \( T_P \), that is, \( T_P = \{ T_a \mid \forall a \in \text{obj} \mathcal{C} \} \).

Differing from \( T_P \) constructed by \( T_a \), each restriction \( P_a \) of \( P \) has the truth and comprehension functor, we do not determine \( P \) itself has a truth and comprehension functor; otherwise, \( P \) has truth and comprehension functor, we also do n’t determine its restriction \( P_a \) has a truth and comprehension functor. In the following, we introduce the definition of a fibered fibration and demonstrate the decidability of \( P \) and its restriction \( P_a \) about the existence of the truth and comprehension functor.

**Definition 19.** Let \( P : T \to \mathcal{B} \) and \( G : \mathcal{B} \to \mathcal{C} \) be two fibrations between small categories, let \( T_P : \mathcal{B} \to \mathcal{C} \) be a truth functor for \( P \), let \( T_P \) have one fibered right adjoint functors \( \langle \cdot \rangle : GP \to \mathcal{C} \), and \( \langle \cdot \rangle \) preserves the Cartesian arrow, then \( P \) is a fibered fibration with a truth functor \( T_P \) and a comprehension functor \( \langle \cdot \rangle \) over \( G \).

Given Definition 18 and Definition 17, the truth functor \( T_P : G \to GP \) of \( P \) is a fibered bifibration, \( T_P \) is fibered right adjoint of \( P \), \( P \) preserves the opposite Cartesian arrow and \( T_P \) preserves the Cartesian arrow. Consequently, it is equivalent that \( P \) is a fibered fibration over \( G \) and that \( P \) is a fibration with a truth and comprehension functor. Then according to Theorem 4 below, we delve deeper into the decidability of fibered fibration \( P \) and its restriction \( P_a \) at \( a \).

**Theorem 4.** Let \( P : T \to \mathcal{B} \) and \( G : \mathcal{B} \to \mathcal{C} \) be two fibrations between small categories, let \( P \) be a fibered fibration over \( G \). Then for \( \forall a \in \text{obj} \mathcal{C} \), a restriction \( P_a : T_a \to \mathcal{B} \) of \( P \) at \( a \) is also a fibered fibration.

**Proof.** Let the fibered adjunction \( T_P \) \( \dashv \langle \cdot \rangle \) be the truth and comprehension functor of the fibered fibration \( P \), respectively. For \( \forall a \in \text{obj} \mathcal{C} \), \( T_a \) and \( \langle \cdot \rangle_a \) is the restriction of \( T_P \) and \( \langle \cdot \rangle \) at \( a \), respectively. With regard to any morphism \( f : a \to b \in \text{Mor} \mathcal{C} \), \( f \cdot T_P^{a \to b} : f^Y : (Y) \to Y \in \text{Mor} \mathcal{B} \) is a Cartesian arrow of \( f \) on fibration \( G \). Now we prove that \( T_a (g^Y) \) is also a Cartesian arrow of \( f \) on fibration \( GP \), i.e.,

![Figure 11 Truth functor T preserves Cartesian arrows](image-url)
truth functor $T_a$ preserves the Cartesian arrow. Let $\exists g: c \rightarrow a \in \text{Mor} C$, let $I \rightarrow X \rightarrow T_a(Y) \in \text{Mor} T_a$ lies above $fg$ (Fig. 11).

Let $\eta: 1_{\mathbf{B}_a} \rightarrow T_a(\{\{\} \})$ and $\varepsilon: \{\{\} \} \rightarrow 1_{\mathbf{B}_a}$ be two natural transformations, and let the transpose $\hat{\varepsilon} = \varepsilon_Y |_l$ of $\varepsilon$ lies above $fg$. Next, in fiber $\mathbf{B}_a$ there exists a unique morphism $\nu(X) \rightarrow f^*(Y) \in \text{Mor} \mathbf{B}_a$ over $g$ such that $f^*_J \cdot \nu = \hat{\varepsilon}$. Henceforth, in fiber $T_a$, we obtain a unique morphism $(T_a(\nu(\eta_Y)) \cdot f^*(Y)) \in \text{Mor} T_a$ over $g$, such that $T_a\left(f^*_J(\nu(\eta_Y))\right) = 1$. So $T_a\left(f^*_J(\nu(\eta_Y))\right)$ is a Cartesian arrow of $f$ on the fibration $GP$. Namely, the truth functor $T_a$ preserves the Cartesian arrows. Similarly, we can also prove the comprehension functor $\{\{\} \}$ preserves the opposite Cartesian arrows by dual principles in [26].

Therefore, we proved $T_a \downarrow \{\{\} \} \cap \mathbf{B}_a$, $\eta$ and $\varepsilon$ are the unit and counit of this adjunction, and $\eta$ is the vertical fibration; the restriction $P_\ast: T_a \rightarrow \mathbf{B}_a$ of $P$ at $a$ is also a vertical fibration.

**Remark 4.** Fibration $G: \mathbf{B} \rightarrow C$ depicts the indexed type, and Theorem 4 ensures if $P: \mathbf{T} \rightarrow \mathbf{B}$ is a fibered fibration over $G$, then for $\forall a \in \text{Obj} C$, the restriction $P_\ast: T_a \rightarrow \mathbf{B}_a$ of $P$ at $a$ is also a fibered fibration with a truth functor $T_a$ and a comprehension functor $\{\{\} \}$, $T_a \downarrow \{\{\} \} \cap \mathbf{B}_a$ in fact, $P_a$ is a subfibration of $P$ [29], i.e., $P_a$ and $P$ have the same fibration structures, semantic behaviors and logical properties.

Similarly to subsection 4.1.2 and 4.1.3, the following are some tools of fibration, including: equation functor, quotient functor and lifting equation-preserving of many-sorted indexed fibration $P_a$.

### 5.2 Semantic Behaviours of Many-Sorted ICDT

**Definition 20.** Let $P: \mathbf{T} \rightarrow \mathbf{B}$ be a bifibration satisfying Beck-Chevalley condition, let $P_a$ be the restriction of $P$ at $a$. Base category $\mathbf{B}$ has products and pullbacks, $G: \mathbf{B} \rightarrow \mathbf{C}$ is a fibration in the indexed category $\mathbf{C}$, and $P$ is a fibered fibration on $G$ with truth functor $T_a$ and comprehension functor $\{\{\} \}$. The diagonal endo-functor $\Delta G: \mathbf{B}_a \rightarrow \mathbf{B}_a$ maps $\forall c \in \text{Obj} \mathbf{C}$ to $c \times c$, the change of base of $P_a$ along $\Delta G$ constructs a relation fibration $\text{Rel}_G(P_a): \text{Rel}_G(T_a) \rightarrow \mathbf{B}_a$ on $G$. Let $\Delta G_\ast: \text{Rel}_G(P_a) \rightarrow \text{Rel}_G(T_a)$ be the lifting equation-preserving of $\text{Rel}_G(P_a)$ on $G$ maps $C$ to $\Delta G_\ast: \mathbf{C}_a \rightarrow \mathbf{C}_a$.

If $EqP_a$ has a left adjoint $Q_{P_a}$ i.e., $Q_{P_a} \downarrow \text{EqP}_a$, then $Q_{P_a}$ is the quotient functor of $P_a$ on $G$.

**Definition 21.** For $\forall a \in \text{Obj} \mathbf{C}$ is an indexed object, the many-sorted indexed fibration $P_a: T_a \rightarrow \mathbf{B}_a$ is the restriction of $P$ at $a$. Let $F: \mathbf{B}_a \rightarrow \mathbf{B}_b$ be an endo-functor in fiber $\mathbf{B}_a$, $F_\ast: \text{Rel}_G(P_a) \rightarrow \text{Rel}_G(T_a)$ be a lifting equation-preserving of $F$ on $\text{Rel}_G(P_a)$. If it satisfies diagram commuting, i.e., $\text{Rel}_G(P_a) \cdot F_\ast = F \cdot \text{Rel}_G(P_a)$, then $\text{EqP}_a \cdot F = F_\ast \cdot \text{EqP}_a$ and $Q_{P_a} \cdot F_\ast = F \cdot Q_{P_a}$.

\[ \forall D \in \text{Obj} \mathbf{B}_a \text{, we can construct an } F \text{- coalgebra } (D, \varphi, D \rightarrow F(D)) \text{ through the action of endo-functor } F. \text{ The equation functor } \text{EqP}_a \text{ of the many-sorted indexed fibration } P_a \text{ maps } (D, \varphi) \text{ to a } F_\ast \text{- coalgebra } (\text{EqP}_a(D), \text{EqP}_a(D) \rightarrow F_\ast(\text{EqP}_a(D))). \text{ If } vF_a \text{ have a carrier of final } F \text{- coalgebras } (vF_a, \text{out}_a: vF_a \rightarrow F(vF_a)). \text{ Then the action of } vF_a \text{ by } \text{EqP}_a \text{ is the carrier of terminal } F_\ast \text{- coalgebra } (vF_\ast, \text{out}_\ast: vF_\ast \rightarrow F_\ast(vF_\ast)). \text{ Since the equation functor } \text{EqP}_a \text{ preserves terminal objects. Similarly for subsection 4.1.4, we write } \text{Coalg}(\text{EqP}_a) \text{ for the functor from } \text{Coalg}_G \text{ to } \text{Coalg}(\text{EqP}_a), \text{Coalgebra } (\text{out}_a) = \text{out}_\ast; \text{ out}_\ast \text{ is the isomorphism mapping to out}_a \text{ with the acting on the functor } \text{Coalg}(\text{EqP}_a). \text{ For any } F_\ast \text{- coalgebra } (Y, \varphi, Y \rightarrow F(Y)) \text{, the quotient functor } Q_{P_a} \text{ of the many-sorted indexed fibration } P_a \text{ maps } (Y, \varphi) \text{ to a } F \text{- coalgebra } (Q_{P_a}(Y), Q_{P_a}(\varphi): Q_{P_a}(Y) \rightarrow F(Q_{P_a}(Y))). \text{ (Fig. 12). Let } n: Y \rightarrow Q_{P_a} \text{ be an } F_\ast \text{- coalgebras morphism from } \varphi \text{ to } \text{EqP}_a(\varphi), \text{ so its corresponding } F \text{- coalgebras morphism } m: Q_{P_a}(Y) \rightarrow D \text{ from } Q_{P_a}(\varphi), \text{ then } F_\ast \text{- coalgebra homomorphism over } n. \text{ Similarly, } n \text{ is a } F_\ast \text{- coalgebra homomorphism over } m. \text{ Functor } \text{Coalg}(Q_{P_a}). \text{ from } \text{Coalg}_G \text{ to } \text{Coalg}_F \text{ establishes an intuitive mutual derivation relationship between } F_\ast \text{- coalgebra, whose carrier is } Y \text{ and } F \text{- coalgebra whose carrier is } Q_{P_a}(Y). \text{ This presents a succinct and coherent model for describing coinductive rule of many-sorted ICDTs, with vF_a as the carrier of terminal F - coalgebra. If the functor } \text{Coalg}(\text{EqP}_a) \text{ preserves terminal objects, then the lifting equation-preserving } F_\ast \text{ of } F \text{ on Rel}_a \text{ generates a sound coinductive rule.}

### 5.3 Coinductive Rule of Many-Sorted ICDT

Let $P: \mathbf{T} \rightarrow \mathbf{B}$ and $G: \mathbf{B} \rightarrow \mathbf{C}$ satisfy the requirements of Definition 20 and Definition 21; let $F: \mathbf{B}_a \rightarrow \mathbf{B}_a$ be an endo-functor in fiber $\mathbf{B}_a$, and $vF_a$ is a carrier of final $F$ - coalgebras. Each lifting which is equation-preserving $F_\ast: T_a \rightarrow T_a$ of $F$ has a sound coinductive rule about $vF_a$, so it ensures the validity of the coinductive rule generated by the many-sorted indexed fibration $P_a$ on a many-sorted...
ICDT. Next we will present and describe the coinductive rule of many-sorted ICDTs with universality in the settings of fibrations.

For $\forall a \in \text{Obj} C$, $\forall D \in \text{Obj} \mathcal{B}_a$, $\phi : (D, \psi : D \rightarrow F(D))$ is a $F$ -coalgebra in fiber $\mathcal{B}_a$ . We construct a corecursive operation $\text{unfold} : (D \rightarrow F(D)) \rightarrow D \rightarrow vF_a$ of a many-sorted ICDT in the base category $\mathcal{B}_a$ on relation fibration $\text{Rel}_a(\mathcal{P}_a)$, and $\text{unfold} \phi$ maps $\phi$ to a sole $F$ - coalgebras morphism $\text{unfold} \phi : D \rightarrow vF_a$ from $(D, \psi)$ to its final $F$ – coalgebras $(vF_a, \text{out}_a)$.

Given property that the equation functor $\text{Eq}_{\mathcal{P}_a}$ preserves terminal objects, and $\text{Eq}_{\mathcal{P}_a}(vF_a)$ is the carrier of terminal $F^+_a$ - coalgebra, write $vF^+_a = \text{Eq}_{\mathcal{P}_a}(vF_a)$ . The isomorphism expression is as the following:

\[ \text{Eq}_{\mathcal{P}_a}(F(vF_a)) = F^+_a(\text{Eq}_{\mathcal{P}_a}(vF_a)) = (vF^+_a) \]

A corecursive operation of a many-sorted ICDT $\text{unfold} : (Y \rightarrow F^+_a(Y)) \rightarrow Y \rightarrow vF^+_a$ is constructed by $F^+_a$ in the total category $\text{Rel}_a(\mathcal{T}_a)$ on relation fibration $\text{Rel}_a(\mathcal{P}_a)$. For any $F^+_a$ - coalgebra $(Y, \phi : Y \rightarrow F^+_a(Y))$, $\text{unfold} \phi$ maps $\phi$ to a unique $F^+_a$ - coalgebra morphism $\text{unfold} \phi : Y \rightarrow vF^+_a$ from $(Y, \phi)$ to terminal $F^+_a$ - coalgebra $(vF^+_a, \text{out}_a)$: $vF^+_a = \text{Eq}_{\mathcal{P}_a}(vF_a)$ . For $\forall D \in \text{Obj} \mathcal{B}_a$, $\forall a \in \text{Obj} C$, $\exists Y \in \text{Obj} \text{Rel}_a(\mathcal{T}_a)$, a coinductive rule of many-sorted ICDT with universality is as follows:

\[ \text{Coind}_a(\mathcal{T}_a) : (Y \rightarrow F^+_a(Y)) \rightarrow Y \rightarrow \text{Eq}_{\mathcal{P}_a}(vF_a) \]

If $\phi : Y \rightarrow F^+_a(Y)$ is an $F^+_a$ - coalgebra over the $F$ -coalgebra $(D, \psi : D \rightarrow F(D))$, then $\text{Coind}_{\mathcal{T}_a}(\mathcal{T}_a) \phi$ is a $F^+_a$ - coalgebra homomorphism over $\text{unfold} \phi$.

5.4 Instance Analysis of Many-Sorted ICDT

Example 5. For any set $A$, let $L^e = L^o \cup L^o$ be the partial order set, including all elements of $A$, where $L^e$ is an infinite set and $L^o$ is a finite set. In turn, we have taken corresponding elements from the even and odd position of $L^e$ to form two partial order sets $\text{EVEN}$ and $\text{ODD}$, with two functions even: $L^e \rightarrow \text{EVEN}$ and odd: $L^e \rightarrow \text{ODD}$ . Then $\text{EVEN}$ and $\text{ODD}$ are mutual recursive many-sorted ICDTs. Let $a, b$ be two indexed objects only in the indexed category $C$ , $a$ is the indexed object of $\text{EVEN}$, and $b$ is the indexed object of $\text{ODD}$. We have defined the endo-functor $F : \mathcal{B} \rightarrow \mathcal{B}$ in the base category $\mathcal{B} = \mathcal{B}$, which is a binary production. For $\forall E \in \text{EVEN}$, $\forall O \in \text{ODD}$, we have $F(E, O) = (O, E)$ . Write $\cdot$ for the merging operation of elements; we have defined the merging property $\text{merge} : \text{merge}(x \cdot \text{EVEN}, \text{ODD}) \rightarrow x \cdot \text{merge}($ \text{ODD}, \text{EVEN})$ ,

\[ \text{even} \left( \text{merge}(\text{EVEN}, \text{ODD}) \right) = \text{EVEN} \]

\[ \text{odd} \left( \text{merge}(\text{EVEN}, \text{ODD}) \right) = \text{ODD} \]

Therefore, the relation on carrier $L^\infty$ of $F$ - coalgebra $R = \{(\text{EVEN}, \text{even}(\text{merge}(\text{EVEN}, \text{ODD}))\}$ and $S = \{(\text{ODD}, \text{odd}(\text{merge}(\text{EVEN}, \text{ODD}))\}$ are a bisimulation.

Let $\text{EVEN}$, $\text{ODD}$ be the carrier $(vF_E, vF_O)$ of terminal $F$ - coalgebra over binary productions in the base category on relation fibration $(\text{Rel}_a(\mathcal{P}_a), \text{Rel}_a(\mathcal{P}_b))$ of the many-sorted indexed fibration $(P_a, P_b)$. For any $F$ - coalgebra $(E, O, m : (E, O) \rightarrow F(E, O))$, is lifted to be a $F^+_a$ - coalgebra $(Y, Y', \phi : (Y, Y') \rightarrow F^+_a(Y, Y'))$ by $(\text{Rel}_a(\mathcal{P}_a), \text{Rel}_a(\mathcal{P}_b))$. This satisfies diagram commuting $(F - \text{Rel}_a(\mathcal{P}_a), \text{Rel}_a(\mathcal{P}_b))(R, S) = ((\text{Rel}_a(\mathcal{P}_a), \text{Rel}_a(\mathcal{P}_b)) - F^+_a(R, S)$ . A corecursive operation $\text{unfold} \phi$ is defined by the terminality of terminal $F$ - coalgebra on $(\text{EVEN}, \text{ODD})$, executing the judgment of a many-sorted ICDT $(\text{EVEN}, \text{ODD})$; another corecursive operation defined by the terminality of terminal $F^+_a$ - coalgebra depicts semantic behaviors of $(\text{EVEN}, \text{ODD})$. If $\phi$ lies above $\phi$, then $\text{Coind}_a(\mathcal{T}_a)$ is a $F^+_a$ - coalgebra homomorphism over $\text{unfold} \phi$. When iterating each property $R \in \text{Obj} \text{Rel}_a(\mathcal{T}_a), S \in \text{Obj} \text{Rel}_a(\mathcal{T}_a)$, $\forall a, b \in \text{Obj} C$ in the total category $(\text{Rel}_a(\mathcal{T}_a), \text{Rel}_a(\mathcal{T}_b))$ on relation fibration $(\text{Rel}_a(\mathcal{P}_a), \text{Rel}_a(\mathcal{P}_b))$, we obtain the semantic set describing properties of $(\text{EVEN}, \text{ODD})$, that is, $(\text{R}(Y), S(Y')) = \text{Eq}_{\mathcal{P}_a}(E), Y' = \text{Eq}_{\mathcal{P}_a}(O)$ .

The mutual recursive type is a complex many-sorted ICDT. Traditional methods, including algebras and category theory, are difficult when effectively processing their semantic computing and program logic. Example 5 analyzes the deeply semantic properties of mutual recursive type using fibrations. The fibration method is not strictly dependent on particular methods or tools, such as predicate logic or set theory, and abstractly depicts its coinductive rule with universality. Example 5 expands and deepens traditional methods in the level of category theory. It deals with the semantic computation of the mutual recursive type in the uniform settings of fibrations, and further develops the width and depth of traditional methods of ICDT in math.

6 CONCLUSIONS

Fibrations integrate conventional ideology regarding programming, with special ideas and studying methods, such as highly abstract, nimble development and brief description, produces a robust and significant effect on program languages and formal semantics, and boosts the application of categorical theory in computer science. There is little literature on fibrations in computer science, especially regarding systematical and deep research aiming at programming; there is even less literature relating to its formal semantics. Fibrations have special superiorities in resolving the representation of speculative matters. At the same time, they are important in the application of theoretical computer science. This paper executed some preliminary works in analyzing semantical behaviors, coinductive rules representation of ICDTs. In general, we expect this work can promote interest for academics particularly in China regarding fibrational method, promoting the prospects of fibration itself and their applications in computer science.

Our future work will be a preliminary discussion on the soundness, completeness, and consistency of a formal system consisting of ICDT and its coinductive rule. Furthermore, we are expanding our ICDT work to include
2-categories using fibrations, with deep discussion regarding math structures and the categorical properties of syntax construction, semantics computation, behaviors description and programming logic in 2-categories.
