Introduction:

Kidney transplantation is the most effective method of renal replacement therapy - the transplanted organ is able to take over all the functions performed by a healthy kidney. The function of the kidney after transplantation should be regularly observed in laboratory tests and imaging examinations. However, in some patients, it is necessary to perform a posttransplant biopsy in order to clearly identify the pathology that may lead to damage to the function of the kidney or transplant rejection.

Aim:

The aim of the study was to assess the type of complications occurring after a biopsy of a transplanted kidney and to assess the effectiveness of ultrasound in diagnosing them.

Materials & Methods:

A retrospective evaluation of the results of US examinations in patients after biopsy of a transplanted kidney was performed in terms of the incidence of complications. All ultrasound examinations were performed in the radiology department with the use of Logiq 7 and Logiq 9 devices in B-mode presentation and in color and spectral Doppler options.

Results:

Complications after biopsy were found in 9 patients: 6 arteriovenous fistulas and 3 hematomas. One of the patients required the embolization of the damaged vessel by the endovascular method.

Conclusion:

Ultrasound examination with the use of Doppler option is an effective method to detect complications after a biopsy of a transplanted kidney, which allows for qualification for endovascular treatment.
