SUMMARY

Effective substation management should include engineering and construction costs. While the construction process has to be methodically planned and sequenced to achieve optimized construction costs, substation designers play a vital role for delivering cost-efficient substations. Integrated design and construction has been proposed as a way to achieve effective project management, which historically viewed, was a responsibility of a “master builder”, thus causing Contractors to identify themselves as “master builders”.

As EPC is a highly competitive arena, Contractors are looking for ways to differentiate themselves from their competitors. Some are turning to 3D technologies, while others turn to the design-construction integration. Virtual Master Builder (VMB) supports both 3D technologies and the design-construction integration. Due to a global shortage of worldwide available expertise, Contractors turn to education and training of their employees. While education aims at providing basic skills, training aims to provide the skill necessary to do the job. This paper examines these basic skills as a part of personal mastery before defining organizational learning as a key organizational competence.

Physical Virtuality realm is seen as a fruitful ground for staging of memorable and transformational experiences leading towards achieving “accelerated learning”, and especially 4D models as representations of a “space-time” environment. The project case of Skopje 4 SS 380/110 kV rehabilitation is given as an example of 4D models usage. Project Engineering is seen as a middle ground between engineering and management in order to achieve goals of effective substation management and cost-efficient substation solutions. Project teams are seen as Virtual Design and Construction (VDC) users to achieve these goals.

KEYWORDS

INTRODUCTION

Ever since the war of currents started, the race to electrify the world has been accelerating [1]. In 2013, the power sector was reported to be a new dominant sector [2]. In a survey, 77 percent of respondents reported underperforming projects due to various causes, but mainly due to project delays, poor estimating practices and failed risk management processes [2].

Effective substation management, as it was warned, should include all relevant cost factors [3], while engineering and construction costs should be included under the cost of acquisition [4]. As according to [5], the cost reduction of Air Insulated Substations (AIS) should focus on minimizing the construction time and on eliminating mis-sequencing of construction activities, which have forces reported such as a shorter construction period to build a new substation, and a requirement for a short installation period. For this, a remedy is advised by means of standardizing both design and construction processes and methods [5]. In order to optimize substation costs, attention should be paid on having accurate and detailed engineering and on having experienced and well-trained construction crews, among others [5]. Generally, for risks related to overexpenditures and delays due to miscoordination at site, mitigation in the form of making schedules of manpower and heavy equipment is advised alongside advising monitoring and adjusting time schedules accordingly [6]. Integrating design and construction has to be methodically planned and sequenced to achieve optimization of construction costs [5]. However, planning the installation of the substation equipment and sequencing it require experience and specialized knowledge [7]. Even though an effective planning of and schedule control system is acknowledged to be of a paramount importance for delivering substation construction projects on time and within the budget [8], it has been found out that scheduling, definition of resources and tracking are the least practiced project considerations [9].

Related to the substation design, a lack of the experienced staff was reported to be a major risk factor due to a limited pool of expertise available worldwide [9]. According to [24], "today’s engineers simply do not possess many of the skill-sets needed to compete internationally". In general, at the level of the industry, there is a lack of qualified managerial and engineering personnel [25]. Contractors do report trouble in filling salaried positions of both engineers and project managers, as hiring is reported to be more difficult when compared to a year ago [26]. These staffing challenges mostly result in higher prices in bids and contracts [26]. As reported inside [2], Contractors are aiming for international expansion where they may suffer from inexperience, lack of technical skills and expertise.

According to [24], "today’s engineers simply do not possess many of the skill-sets needed to compete internationally". In general, at the level of the industry, there is a lack of qualified managerial and engineering personnel [25]. Contractors do report trouble in filling salaried positions of both engineers and project managers, as hiring is reported to be more difficult when compared to a year ago [26]. These staffing challenges mostly result in higher prices in bids and contracts [26]. As reported inside [2], Contractors are aiming for international expansion where they may suffer from inexperience, lack of technical skills and expertise.

Contractors are also mostly inclined towards initiating or increasing inhouse training, and towards providing of career-building programs [education] [26]. While “training” aims to develop knowledge, skills and abilities to do the work, “education” aims to develop critical and basic skills [27]. According to [26], the workplace of tomorrow should have critical thinking skills, complex problem-solving skills, and judgement and decision-making skills.

PERSONAL MASTERY

CRITICAL THINKING SKILL

Critical thinking skill is defined as “using logic and reasoning to identify strengths and weaknesses of alternative solutions, conclusions, or approaches to problems” [30]. Deductive and inductive reasoning are two examples of reasoning [31], thus comprising critical thinking.

Term “Renaissance Engineer” is being used as a new vision for the engineer of the third millennium, and there is a tendency for engineering students to undertake some liberal education [32]. Historically viewed, engineering education as such was inseparable from learning liberal arts [33]. Engineering personnel [25]. Contractors do report trouble in filling salaried positions of both engineers and project managers, as hiring is reported to be more difficult when compared to a year ago [26]. Contractors are also mostly inclined towards initiating or increasing inhouse training, and towards providing of career-building programs [education] [26]. While “training” aims to develop knowledge, skills and abilities to do the work, “education” aims to develop critical and basic skills [27]. According to [26], the workplace of tomorrow should have critical thinking skills, complex problem-solving skills, and judgement and decision-making skills.
According to [36], learning inside each loop focuses on answering to a specific question, namely: what should we do, how should we do it, and why should we do it. Single-loop learning represents means-end thinking in which ends are set with a goal to discover the best means for meeting those ends, and these single-loop learners are task-oriented [36]. While single-loop learners perceive that identification of ends and the best means to achieve them is not problematic, for double-loop learners the definition of ends and means is problematic, as ends become accommodations or reconciliations among people [36]. Double-loop learning is depicted inside Figure 4. With double-loop learning a new consciousness is created between two centers of learning and is marked as “C,” thus causing de-emphasising of the task-oriented nature in favor of a wider perception of the task [36].

A new consciousness is also created with triple-loop learning for the purpose of being able to operate more intelligently and responsibly through increasing the fullness and depth of learning [36], and is depicted inside Figure 5. In general, triple-loop learning is also concerned with a wider perception of the task, but with the purpose of creating a fairer practice, usually by resolving issues and managing dilemmas when facing them [36]. These issues and dilemmas may arise due to a collision in definition of ends and means as these are treated as non-problematic inside single-loop leaning and treated as problematic inside double-loop leaning.

There has been a reminder that engineering is a service profession which should take into account other factors beyond technical factors such as economic, social, environmental etc. when critically examining a problem [34]. An example of practicing a holistic view of design through different learning loops is given inside Figure 6.

While single-loop learning supports minor fixes or adjustments within governing variables, double-loop learning supports major fixes during which governing variables as deep-level variables are usually changed [37]. It is triple-loop learning that strives to “satisfice” when they are acting [49]. These governing variables represent variables that can be inferred [49]. Governing variables as deep-level variables are usually changed [37]. These issues and dilemmas may arise due to a collision in definition of ends and means as these are treated as non-problematic inside single-loop leaning and treated as problematic inside double-loop leaning.

The requirement for double- and triple-loop learning resonates with the role of a design engineer, which according to [9], should study each situation to find an appropriate solution in order to spare resources, but also to learn about alternative available techniques that support realizing the optimum substation design solution. Such unique ideas / solutions can be achieved by examining and altering the governing variables (preferred state) first before experimenting with single-loop learning [36]. It is triple-loop learning that goes beyond scientific insight and patterns towards the holistic view of economic, social, cultural and other factors, thus creating a shift in understanding the context or point of view for the purpose of understanding how problems and solutions are related [37].

In essence, multiple loops from Figure 6. converge into a design solution [37].

According to [43], many design problems are so ill-defined and complex with uncertainties associated to both, the ends and means of a potential solution. The entire construction process is riddled with uncertainties thus making it an ill-defined problem in its entirety [44]. Available technical tools [the existing professional body of knowledge] are seen as insufficient to manage complicated and complex projects [45], and the project manager alone cannot be a sole hero of a project anymore [46]. “Artificial tools and methods” alongside “Cannot try before build” are stated to be some of the reasons making construction a risky business [47]. Figure 2. depicts our view of a modern professional when facing ill-defined problems that require solving.

Designers, engineers and managers are reflective practitioners who deal with “messy” situations by means of conducting a conversation with the unique situation at hand trying to make sense of the problematic situation [48]. As the situation is complex and uncertain, there is a problem to find the problem [48]. Constructing and understanding the situation is the first thing to do in order to find the problem by reframing the problematic situation into one dealt with before, as a new problem is seen as a variation of an older problem [48]. It is these built-up repertoires of examples / understandings / actions that are built by previous experiences through practicing reflection-in-action [48]. Reflection-in-action necessarily involves experimentation as an activity to see where the action leads to, but fundamentally it answers the question “what if” [48]. In essence, such an exploratory experiment involves experimentation, move-testing and hypothesis testing [48]. Problem solving, as such, is only a part of a larger experiment in problem setting [48]. Reflection-in-action for managers is fundamentally similar to reflection-in-action practiced by designers and engineers for resolving “messes” [48], as sets of interacting problems within complex systems [41].

**JUDGEMENT AND DECISION-MAKING SKILL**

Judgement and decision-making skill is defined as “considering the relative costs and benefits of potential actions to choose the most appropriate one” [30].

Governing variables are defined as preferred states that interventionist strive to “satisfice” when they are acting [49]. These governing variables do not represent deeper underlying beliefs of an interventionist, but do represent variables that can be inferred [49]. Governing variables as deeper beliefs are accustomed to triple-loop learning.

When a match or a mismatch exists between the preferred state (governing variables) and the consequence of actions exist that is corrected by changing actions, it is said that single-loop learning has occurred in that case [49]. Double-loop learning occurs when mismatches are corrected by examining and altering the governing variables (preferred state) first and then through action [49]. Double-loop learning will be required for a practitioner to solve a complex problematic situation, instead of single-loop learning [50].

According to [51], decision-making process in its simplest form can be—
scribed as “finding the best solution among the set of alternatives having sound preferences that trigger the right course of action”.

For the power substation design, as according to [51], using existing repertoires of action based on the standardization is closely related to the practice of standardized equipment, standardized designs and standard substation layouts, thus relating to agile companies, and namely agile Utilities. This is depicted by the blue line inside Figure 8, which allows deciding stage of the decision-making process to be skipped [51]. It is also argued inside [51] that all other companies differing from agile Utilities cannot skip the decision stage inside the decision-making model, in order to identify the best solution as the most cost-efficient one. Figure 8 is based on Boyd’s Observe-Orient-Decide-Act (OODA) loop as a single-agent model for dynamic decision-making, and the Orient stage is of the paramount importance in an agile decision-making model as it “guides” observation of information and “drives” decisions and actions [51]. Lean Project Delivery System (LPDS) is placed at the center of Orient stage, making it a core of a decision-making model when pursuing optimization / cost efficiency [51].

For the purpose of this paper, a green arrow between Lean Assembly and Lean Design represents application of constructability. In order to arrive to the best solution [with an exception of utilization of the blue line], cycling through feedback loops is inevitable [51].

CORRELATING ABILITIES FOR TEAMS

While deductive reasoning is largely covered by available scientific tools, available scientific tools still do not cover the majority of inductive reasoning. For that purpose, we assume that individual skills covered inside chapter 2.2, are taken as skills relevant for personal mastery, as according to [52], personal mastery is about seeing the reality objectively.

Figure 9. depicts core learning capabilities for teams and personal mastery is one of them.

Personal mastery is a base for developing of a shared vision which usually represents shared “pictures of the future” that foster commitment [53]. According to [53], people today are no longer satisfied with “just having a job”, but are multi-functional, flexible, talented and most importantly, goal-oriented. A move towards self-directed and self-sufficient teams consisting of multi-skilled individuals was proposed to large hierarchical systems as an opposition to demanding compliance [53]. “Creeing managerialism” is a problem of today’s project management [47]. While the empowering staff has been reported to be the most powerful force behind the substation cost reduction [39], on the other hand commitment was identified as an enabler of a drastic compression in the schedule [38]. Another core learning capability for a team is team learning [52]. Team learning is about developing skills of groups of people to see a larger picture laying harbors that trigger the right course of action.

OVERCOMING “LEARNING HORIZON” AND THE MULTIVERSE

While personal mastery is seen as an essential cornerstone of organizational learning and its spiritual foundation, system thinking is seen as its capstone that integrates other four core learning capabilities and provides insights for understanding complexity [52]. Within complex systems, decisions and consequences of actions are distant in space and time, preventing in such a way gradual development of learning and maintaining a direct experience as a result of the “learning horizon” [52].

While Senge spoke about “microworlds” as the technology for the Learning Organization [52], Schön spoke of “virtual worlds” for professional practice and development through practice of reflection-in-action [48]. Underlying similarity of both of these “worlds” is the ability to allow “compression of time and space”, isolation of variables for experimentation purposes involving cause-effect simulations, move-probing and hypothesis-testing, all conducted inside such a “world” as a risk-free environment, enabling removal of pressures associated with real decision-making in regards to suffering that consequences of selected actions. That are exactly those “worlds” as environments that can provide a unique insight into the future.
overcoming limitations imposed by the “learning horizon”, and enabling in such a way a development of learning from direct experiences [52].

Organizational learning is regarded as a competence all organizations should develop [49]. Organizations themselves do not learn but are able to create conditions for individuals to learn effectively [49]. Created conditions should support development of double-loop learning [49].

According to the progression of the economic value, services can stage experiences and experiences can guide transformations [60]. When three new axes of “no-space”, “no-time” and “no-matter” are added above axes of “space”, “time” and “matter”, the concept of a Multiverse is created comprising eight realms all of which are capable to stage experiences [60], and those experiences are formed through five human senses [41].

The concept of Multiverse is depicted in Figure 13. The focus of this paper is placed in the realm of Physical Virtuality, “Instantiating the virtual in the material, Physical Virtuality takes an experience happening in a virtual place and then instantiates, or realises, it in the real world; first you dream it, then you build it”, and it is the domain of the Computer Aided Design (CAD) software [60].

PHYSICAL VIRTUALITY FOR SUBSTATION DESIGN AND CONSTRUCTION

It was believed that Virtualization Technology (VT) can reduce the cost of design, construction and maintenance of major facilities such as substations [61]. 3D modelling was seen as a door opening up new avenues for efficient substation construction [62]. Incorporation of three-dimensional models (models used to design substation design simplifies the design process and allows non-technical professionals to have a better understanding of the design concept [63]. Fly-through and walk-throughs are helpful for receiving opinions including accessibility and constructability, with a final goal to reduce potential design errors due to unforeseen construction expenses and delays [62]. The construction crew can be thus involved during the design process giving suggestions and helping to identify problems [39], as the coordinated system of construction minimizes the time and the cost required for detailed engineering and field assembly [64]. 3D model-based approach provides means for gaining and exploring “the big picture” [65]. 3D model-based approach provides means for gaining and exploring “the big picture” [65]. The concept of Multiverse is depicted in Figure 13. The focus of this paper is placed in the realm of Physical Virtuality, “Instantiating the virtual in the material, Physical Virtuality takes an experience happening in a virtual place and then instantiates, or realises, it in the real world; first you dream it, then you build it”, and it is the domain of the Computer Aided Design (CAD) software [60].

Design tools enable users to experience differences between options and possibilities through visualization [60]. However, 3D visual design tools are not enough in many situations and should include the fourth dimension of time added onto a virtual 3D model to make experience memorable and transformational when compared to the experience associated to 3D models only [60]. Those models with the time dimension associated to three spatial dimensions are being referred to as 4D models [60].

4D models represent a graphic simulation of the construction process in a determined time unit [57], as 4D model is made from a combination of a 3D model with an activity / task from a Gantt chart [68].

The process of substation construction and installation is suggested as a topic to be included in the training materials [69]. As advised according to [11], recurring construction problems on substations can be resolved using conventional managerial approaches including training and careful planning. Training materials should focus on the topics of how to plan the job, how to develop a realistic schedule, how to track the progress and spot potential problems [70]. Such training materials dealing with real-life requirements for tasks involving design and construction substation projects are mostly not available as “off-the-shelf” products and should be developed internally by the company [70], while being visually enhanced as much as possible [69].

VT has been believed to be an enabler of a greater reduction of costs for training while increasing the productivity of training Transmission and Distribution (T&D) personnel [61]. Building Information Modelling (BIM) tools have allowed engineers to improve their response capacity and provide the faster learning curve for new substation designers [57].

“Accelerated learning” and accelerated training have been reported as advantages of 3D substation design software as these can capture some of the experience of the retired workforce [71]. 3D substation design tools have been seen as a design process improvement [72].

BIM AND VIRTUAL DESIGN AND CONSTRUCTION

3D models are seen as facilitators of interdisciplinary coordination [65], which is stated to be one of the prime benefits of BIM [67]. BIM is also seen as an enabler of a greater collaboration among the design and construction disciplines, but also as a platform for collaboration throughout the project design and construction [25]. In general, BIM has been seen as a “transformational trend” [23], as proven advantageous to project teams [63]. From the context of substation design, BIM is defined as a tool used “to determine critical cost factors in the early substation planning phase, shift the time, effort and cost structures to earlier phases in the substation planning – enabling better decision making” [73]. Decision-making models should be transformed leaving behind models of “linear thinking” in favour of embracing shared understanding of interrelationships. In general, decisions are made based on available information / knowledge, thus meaning that management of a construction project is about managing the project information flow [47]. Just “ineffective information / knowledge management” is one of the reported problems of the contemporary project management rooted inside a lack of a uniform platform where information / knowledge can be stored and retrieved as wished [47].

For VDC practice, BIM is viewed only as an “information model” and two core information models are relevant, namely design intent models and construction models [74]. While design intent models are created for the purpose to visualize and understand the integration of all different systems [74], construction models are created with a greater level of detail to represent what is actually installed [74]. Construction model can also represent the existing conditions for brownfield projects [74].

Generic overview of a VDC practice diagram is given inside Figure 14.

![Figure 4. Generic overview of VDC practice diagram as based on [74]](https://doi.org/10.37798/202069448)

Construction management (CM) and VDC models as a mixture of both design intent models and construction models ensure that intended designs are built in the best possible way, at the lowest cost and in the most time-efficient manner [74]. These models include 3D information model, visualization models / experience simulation models (walkthroughs and flythrough), coordination models as a composite model (primarily used for clash detection between systems and for constructability reviews), cost and quantification models (in which quantity information is connected to quantity calculations and then linked to a cost estimation database), 4D models (for visualizing schedule and understanding construction sequencing), logistics models, and testing models (comparing actual site work progress with planned progress) [74].

The concept of as-built models for operation is similar to a “digital twin” concept.

VDC model types are used as a base for realization of VDC services [74]. According to [74], and depending on a VDC model, these services are typically related to:

- For 3D information model, VDC services may include: model quality control, constructability studies, virtual mockups, field capturing, etc.
we draw a parallel between communication, coordination, and cooperation with these as interaction types from chapter 2.8, but we also draw a parallel between VMB and VDC / BIM, and the following is argued:

- VMB concept is reflected inside a VDC concept;
- Differentiation level is achievable through utilization of 4D VDC models and will have an impact on business processes and organizational and employee culture;
- Business processes should be changed to support integration wherever possible;
- Employees should focus on personal mastery and on developing individual skills;
- Organizations should use collective mechanisms to develop agile project teams;
- Organizational learning is a key competence for delivering substantive projects, and;
- VDC is an enabler of “accelerated learning” and of meaningful experiences to all.

Following current trends, the company has embarked on a “differentiation journey” with VDC.

PROJECT CASE FOR SS 380/110 kV SKOPJE 4 REHABILITATION

Skopje 4 SS 380/110 kV was first 380 kV substation to be built on the territory of Republic of North Macedonia during the 1970’s, as a part of former Yugoslavian “Nikola Tesla” 380 kV ring. The rehabilitation scope included replacement of almost all 110 kV primary equipment, replacement of the majority of 400 kV primary equipment, the relay house rehabilitation, rehabilitation of cable trenches and their covers (where necessary), replacement of secondary equipment and of AC/DC systems, with a requirement for installing of a completely new cabling. Due to the difference in today’s standards and regulations compared to ones from the 1970’s, and in order to arrive to the best solution that satisfies all the relevant requirements, a double-loop learning was a necessity due to requirement for examination of governing variables. These governing variables were related to voltage and safety clearances, sag and wire tension definition, environmental conditions, load combination on the conductors, influence of spacers on the value of forces due to a three-pole short-circuit, etc. Seeking answers relating to what, how and why was a necessity. In order to do so, both 3D substation design intent models and a 3D construction model (depicting existing situation) were created inside “primtech”. Examination of governing variables was conducted inside “primtech” utilizing integrated calculations, interference checks and clash detection. Furthermore, VDC models as a 3D coordination model and 4D model were created for the purpose of conducting constructability reviews and optimizing construction sequencing. Figure 16. depicts a 3D model used for two 110 kV OHL bays with installation process depicted as a green color. Knowledgeable construction personnel were brought up-front with the design team and were treated as a separate technical discipline inside our project team, thus enabling our design team to focus on standardizing designs and materials, supporting ease of installation. As a result, an updated construction methodology document was created and construction activities were defined more accurately. The usage of resources was also defined more accurately, leading to the construction schedule optimization. “Information model” became the project team’s hub.

That has led to connection of patterns not previously linked, as a definition of creativity [41].

Creativity is stated as one of the skills required for the future workforce [29]. Let us create...
CONCLUSIONS

Virtual Master Builder (VMB) as a concept for organizational integration through communication, coordination and cooperation [22], is available for project teams through Virtual Design and Construction (VDC) [74]. VDC is seen as a solution supporting effective project management [47], through which problems on substation projects reported inside [11] can be addressed. VDC is seen as an enabler of meaningful experiences that guide transformations towards delivery of substation projects on time, within a budget and of a required performance, supporting recommendations given inside many of CIGRE SC B3 TBs, and especially those given inside TB 740. It is up to Contractors to provide environments, change processes and deal with “organizational defences” to support VDC application on power substation projects, enabling delivery of cost-effective substation by pursuing differentiation. Individual competencies should be translated into collective ones [46].

RECOMMENDATIONS

Future papers on this topic could relate to introduction and utilization of five-dimensional (5D) BIM models (4D + cost) for power substation design and construction. Utilization of 5D BIM models could be put in the context of Value Engineering. Definition of VDC practice diagram and process for five-dimensional (5D) BIM models (4D + cost) for power substation design and a breakthrough in planning would need to think in a systems manner [41], and have a breadth of vision [42]. While the “master builder” is about being in charge and in control of all aspects of the project [17], Project Engineering is about integration of these aspects of EPC project [71]. Here, we see Project Engineering at the middle ground between design and construction stage, but also between engineering and management roles. Engineering, like the rest of professions, is a mix of both “art” and “science” [9]. According to [8], “the art of knowing what works best in each situation, which is gained through experience, will guide the “science” to achieve its best results.” This definition of “art” resembles to definition of art, according to [48], as a skill for action relating to “knowing (reflection)-in-action”. Knowledge as such is a set of mental models [41], which guides the decision-making process [69]. In order to achieve cost-efficient substation solutions, mental models should be aligned with LPDS. For that purpose, we see a man standing on the LPDS body of knowledge on Figure 17. Under definition of “science” we understand the usage of specialized scientific tools. His left hand is immersed into multidiscipline engineering professions, thus merced into project and construction management professions, while his right hand is immersed into multidisciplinary engineering professions, thus utilizing agile decision-support tools to perform tasks inside a dynamic and complex environment. In doing so, he strives to achieve the “unity of opposites” inside of a “space-time” environment, obtaining the “master” in his practice through learning-by-doing involving experimentation as double- / triple-loop learning, thus leading to a personal transformation from unnatural and troubled state depicted inside Figure 2. to a natural and self-confident state depicted inside Figure 17. as a representation of the Universal man striving for self-realization following the middle path, one that we identify here as Project Engineering. Figure 17. is based on notes by Vitruvius, Roman master builder.

ACKNOWLEDGEMENTS

During 2019 while envisioning the title and the scope of this paper, the authors were inspired by [78], 40 years after the anniversary of a historical icon, when in 1979 when the top of Mt. Everest was ascended by opening a new “West Ridge Direct” route, which according to [78], may represent the most difficult route to the top. It is this idea of walking on the edge to balance between emphasised government and efficiency and creativity and responsiveness in organizational systems, which could, according to [79], generate new forms of work and methods of achievement. A fine example of this is a sheer personal willpower coupled with 3D modelling, constructing sequencing and various analysis tools, which according to [80], have transformed engineering, in turnkey projects in Taiwan: An Empirical Study of Power Distribution Substation Projects” (Project Management Journal, Vol. 43, No. 3, June 2012, pages 50-61).

To knowing oneselfs.
