Significance of Calcifications in Projection of Carotid Arteries on Orthopantomography for Detection of Carotid Artery Stenosis

Značaj prikaza vrijednosti kalcifikacija u projekciji karotidnih arterija na ortopantomogramu u otkrivanju stenoze karotidnih arterija

Abstract

Introduction: Orthopantomography is amongst the most commonly used dental imaging modalities. Calcifications in the projection of carotids on orthopantomographs are found in 3-15% of general population and commonly represent calcified atherosclerotic plaques. Carotid atherosclerotic changes are one of the most frequent causes of stroke, which is the second most common cause of death and the leading cause of disability globally. Our aim was to determine the relationship between calcifications in the projection of carotids on orthopantomographs, carotid stenosis and stroke, and the correlation between stroke risk factors, calcifications on orthopantomographs and the degree of carotid stenosis. **Materials and methods:** Doppler ultrasound and brain MRI were performed in 41 patients with unilateral or bilateral calcifications on orthopantomographs. Anamnestic data relevant to stroke risk were gathered. **Results:** Significant stenosis >50% was found in almost 15% of our patients. There was a significant correlation between hypertension and carotid calcifications. No statistically significant correlation between calcifications and significant stenosis was found. Patients with previous stroke were approximately 5 years older than those without stroke. **Conclusion:** Preliminary results show no statistically significant correlation between calcifications on orthopantomography and significant carotid stenosis, but further investigation is needed.

Introduction

Stroke is the second most common cause of death and the leading cause of adult disability worldwide. In 2019, there have been 12.2 million strokes and 6.5 million stroke-related deaths globally (1,2). There are 1.1 million strokes and consequently 440.000 deaths in the European Union annually (3).

Atherosclerotic changes of extracranial arteries, especially carotids, are one of the most common causes of stroke. They are associated with clot formation at the site of a plaque or, more commonly, with the embolization distally, and

Uvod

Moždani udar drugi je najčešći uzrok smrti i vodeći uzrok invalidnosti u odrasloj populaciji u svijetu. U 2019. godini globalno je bilo 12,2 milijuna moždanih udara i 6,5 milijuna smrti povezanih s moždanim udarom (1, 2). Na godinu u Europskoj uniji od moždanoga udara oboli 1,1 milijun ljudi, a posljedično umre 440 000 (3).

Aterosklerotske promjene ekstrakranijalnih arterija, posebice karotida, jedan su od najčešćih uzroka moždanoga udara. Povezane su sa stvaranjem ugruška na mjestu plaka ili će-

therefore responsible for approximately 50% of all ischemic strokes (4). The most important risk factors for atherosclerosis are age, male sex, hypertension, dyslipidemia, diabetes mellitus, high body mass index (BMI), metabolic syndrome, previous cardiovascular and cerebrovascular diseases, hypercoagulative state, physical inactivity and smoking (5,6). Atherosclerotic changes of carotids are most commonly found at the bifurcation and in the proximal 1-2cm of the internal carotid artery (7,8). The plaques can calcify and thus can be seen radiographically.

Orthopantomography (OPG) is one of the most frequently used X-ray imaging methods in dental medicine. Due to its large field of view, the most susceptible area for carotid atherosclerotic plaques is shown on most OPGs. Calcified plaques are usually seen as one or more nodular, vertical or irregular mineral opacities, 1.5cm inferior and 2.5cm posterior to mandibular angle, at the level of C3 and C4 vertebra, unilaterally or bilaterally (8,9). They should radiomorphologically be differentiated from the hyoid bone, styloid process, thyroid cartilage, epiglottis, stylohyoid and stylomandibular ligament calcifications, tonsiloliths, sialoliths, calcified lymph nodes, and especially the triticeal cartilage (8-14). The prevalence of calcifications in the projection of carotids on OPGs ranges from 3-15% in general population (4,8,12,15,16), but it is higher in diabetics, persons with metabolic syndrome (11,17), in physically inactive individuals (18) and smokers (18,19).

Color Doppler ultrasound (CD-US) is considered to be the method of choice for diagnosing carotid artery atherosclerotic changes, and determining their degree of stenosis by numerous authors (4,5,16,19), due to its high sensitivity and specificity (98%, respectively 88% for PSV (*peak systolic velocity*) $\geq 130\text{cm/s}$ and stenosis $\geq 50\%$, and 90%, respectively 94% for PSV $\geq 200\text{cm/s}$ and stenosis $\geq 70\%$) (20). It is highly-available and allows for the real-time analysis of vessel morphology, inner plaque structure, blood flow direction and velocity, as well as the estimation of the stenosis degree.

Brain magnetic resonance imaging (MRI) is the dominant imaging modality for brain parenchyma due to its superior contrast resolution for soft tissues, and therefore is a very sensitive method for detecting the signs of brain vessel atherosclerotic disease and stroke.

A number of studies have mentioned the clinical importance of noticing the calcifications in the projection of carotids on orthopantomographs (4,5,11-13,15,20) due to the correlation between the atherosclerotic carotid plaques and stroke (5,6,11,12,21), but the relationship between the calcifications and the significant carotid artery stenosis ($>50\%$) remains indeterminate (4,15,22-24).

In this study we evaluated the correlation between the calcifications in the projection of carotid arteries on OPGs and the carotid stenosis degree on CD-US. Our hypothesis was that the presence of calcifications in the projection of carotids on OPGs indicated a carotid stenosis $>50\%$ on CD-US. We also analyzed the relationship between stroke risk factors, calcifications in the carotid artery projection on OPGs and the degree of carotid stenosis, as well as the frequency of gathered sociodemographic data, habits and previous

šće s distalnom embolizacijom, te su odgovorne za približno 50 % ishemijskih moždanih udara (4). Najvažniji čimbenici rizika za aterosklerozu su dob, muški spol, hipertenzija, dislipidemija, dijabetes melitus, visoki indeks tjelesne mase (BMI), metabolički sindrom, prethodne kardiovaskularne i cerebrovaskularne bolesti, hiperkoagulativna stanja, tjelesna neaktivnost i pušenje (5, 6). Aterosklerotske promjene karotida najčešće se nalaze na bifurkaciji i u proksimalnih 1 do 2 cm unutarnje karotidne arterije (7, 8). Plakovi mogu kalcificirati i stoga biti vidljivi na rendgenskim snimkama.

Ortopantomografija jedna je od najčešće korištenih rendgenskih slikovnih metoda u dentalnoj medicini. Područje karotidnih arterija najpodložnije nastanku aterosklerotskih plakova vidi se na većini ortopantomograma zbog velikoga polja snimanja. Kalcificirani plakovi obično se prikazuju kao jedno ili više nodularnih, vertikalnearnih ili nepravilnih mineralnih zasjenjenja 1,5 cm inferiorno i 2,5 cm posteriorno mandibularnom kutu, u razini kralježaka C3 i C4, jednostrano ili obostrano (8, 9). Radiomorfološki potrebno ih je razlikovati od jezične kosti, stiloidnoga nastavka, tireoidne hrskavice, epiglotisa, kalcifikacija stilohioiodnoga i stilomandibularnoga ligamenta, tonsilolita, sijalolita i kalcificiranih limfnih čvorova, a posebno triticealne hrskavice (8 – 14). Prevalencija kalcifikacija u projekciji karotidnih arterija na ortopantomogramima kreće se od 3 do 15 % u općoj populaciji (4, 8, 12, 15, 16), ali je veća u dijabetičara, osoba s metaboličkim sindromom (11, 17), tjelesno neaktivnih osoba (18) i pušača (18, 19).

Obojeni dopplerski ultrazvuk (CD-UZV) mnogobrojni autori (4, 5, 16, 19) smatraju metodom izbora za dijagnostiku aterosklerotskih promjena karotidnih arterija i određivanje stupnja stenoze zbog njegove visoke osjetljivosti i specifičnosti (98 %, odnosno 88 % za najvišu sistoličku brzinu – PSV (engl. *peak systolic velocity*) $\geq 130\text{ cm/s}$ i stenozu $\geq 50\%$, te 90 %, odnosno 94 % za PSV $\geq 200\text{ cm/s}$ i stenozu $\geq 70\%$) (20). To je visoko dostupna metoda koja omogućuje analizu morfologije krvnih žila, unutarnje strukture plaka, smjera i brzine protoka krvi u stvarnom vremenu i određivanje stupnja stenoze arterije.

Magnetska rezonancija (MR) mozga dominantna je slikovna metoda za prikaz moždanoga parenhima zbog visoke kontrastne rezolucije za meka tkiva pa je zato vrlo osjetljiva za prikaz moždanoga udara i znakova aterosklerotskih promjena krvnih žila u mozgu.

U nizu studija autori ističu kliničku važnost uočavanja kalcifikacija u projekciji karotidnih arterija na ortopantomogramima (4, 5, 11 – 13, 15, 20) zbog povezanosti aterosklerotskih plakova karotida i moždanoga udara (5, 6, 11, 12, 21), no korelaciju kalcifikacija i značajne stenoze karotidnih arterija ($>50\%$) još je uvijek nedovoljno istražena (4, 15, 22 – 24).

U ovoj studiji ispitivana je povezanost kalcifikacija u projekciji karotidnih arterija na ortopantomogramima i stupnja karotidne stenoze na CD-UZV-u. Postavljena je hipoteza da prisutnost kalcifikacija u projekciji karotidnih arterija na ortopantomogramu upućuje na stenu karotidnih arterija $> 50\%$ na CD-UZV-u. Analiziran je i odnos čimbenika rizika za moždani udar, kalcifikacija u projekciji karotidnih ar-

cerebrovascular/cardiovascular diseases of the examinees. The prevalence of stroke on brain MRI among the patients with carotid artery calcifications has also been investigated, as well as the difference among the risk factors and the stenosis degree between the patients with the stroke and the patients with no previous stroke.

Material and methods

The study has been conducted at the Department of General and Dental Radiology, School of Dental medicine, University of Zagreb, and at the Department of Diagnostic and Interventional Radiology, University Hospital Center (UHC) Sestre milosrdnice in Zagreb. It has been approved by the Ethics Committee of UHC Sestre milosrdnice in Zagreb, and by the Ethics Committee of School of Dental Medicine, University of Zagreb.

Participants

Examinees in this study were patients with either unilateral or bilateral calcifications in the projection of carotids on the OPGs. All OPGs were previously taken due to dental indications, at the UHC Sestre milosrdnice and at the School of Dental Medicine, University of Zagreb. The patients have all been informed and have consented to participate in the study.

We are showing the preliminary results of this study, gathered on 41 patients.

Procedures

743 digital OPGs in DICOM format, obtained in September and October 2021, have been analyzed by a board-certified radiologist, using the digital orthopantomography software (Scanora). Unilateral or bilateral calcifications in the projection of carotids, radiomorphologically suspicious for atherosclerotic plaques (Figure 1), have been detected in 60 patients (8,07%). 41 patients consented to participate in the study and fulfilled the study inclusion criteria (no contraindications for MRI, 50 year old or older).

CD-US of carotid arteries and the brain MRI have been performed at the Department of Diagnostic and Interventional Radiology, UHC Sestre milosrdnice, Zagreb, Croatia. Carotid CD ultrasound was performed using a GE Healthcare Logiq S8 from 2018, and MRI with a Siemens Aera 1.5T

terija na ortopantomogramima i stupnja karotidne stenoze i učestalost prikupljenih sociodemografskih obilježja, navika i dosadašnjih cerebrovaskularnih/kardiovaskularnih bolesti ispitnika. Također smo željeli odrediti prevalenciju preboljeloga moždanoga udara na MR-u mozga bolesnika s kalcifikacijama karotidnih arterija te razliku između čimbenika rizika i stupnja stenoze bolesnika s preboljelim moždanim udarom i onih bez prethodnoga moždanog udara.

Materijal i metode

Istraživanje je provedeno na Katedri za opću i dentalnu radiologiju Stomatološkog fakulteta Sveučilišta u Zagrebu te u Zavodu za dijagnostičku i intervencijsku radiologiju KBC-a Sestre milosrdnice u Zagrebu. Odobrilo ga je Etičko povjerenstvo KBC-a Sestre milosrdnice te Etičko povjerenstvo Stomatološkog fakulteta Sveučilišta u Zagrebu.

Ispitanici

U istraživanje su uključeni pacijenti s jednostranim ili obostranim kalcifikacijama u projekciji karotidnih arterija na ortopantomogramima. Ortopantomogrami su snimljeni zbog stomatoloških indikacija u KBC-u Sestre milosrdnice i na Stomatološkom fakultetu Sveučilišta u Zagrebu. Svi ispitanici pristali su sudjelovati u studiji i potpisali su informirani pristanak.

Prikazani su preliminarni rezultati studije prikupljeni za 41 pacijenta.

Metode

U rujnu i listopadu 2021. snimljena su 743 digitalna ortopantomografi u DICOM formatu koja su pregledali specijalisti kliničke radiologije koristeći softverom za digitalnu ortopantomografiju (Scanora). Unilateralne ili bilateralne kalcifikacije u projekciji karotidnih arterija, radiomorfološki suspektnye za aterosklerotske plakove (slika 1.), otkrivene su kod 60 pacijenata (8,07%). U istraživanju je pristao sudjelovati 41 pacijent s ispunjenim kriterijima za uključivanje u studiju (bez kontraindikacija za MR, 50 godina ili više).

CD-UZV karotidnih arterija i MR mozga učinjeni su u Zavodu za dijagnostičku i intervencijsku radiologiju KBC-a Sestre milosrdnice, Zagreb, Hrvatska. Ispitanici su pregledani dopplerskim ultrazvukom na uređaju GE Healthcare Logiq S8 iz 2018. godine, a MR mozga učinjen je na aparatu Sie-

Figure 1 Orthopantomograph showing calcifications in projection of carotids, suggestive of calcified atherosclerotic plaques.

Slika 1. Ortopantomogram pokazuje kalcifikacije u projekciji karotidnih arterija koje upućuju na kalcificirane aterosklerotske plakove

from 2018. The exams were conducted and read by experienced radiologists.

Bilateral common, internal and proximal external carotids have been examined with ultrasound, using a linear, high-frequency probe. Grayscale ultrasound, CD ultrasound and spectral analysis have been performed. The flow velocities and arterial spectres in common carotid artery (CCA), internal carotid artery (ICA) and external carotid artery (ECA) on both sides have been determined, as well as the degree of stenosis. The patients have been divided into two categories – the first group consisted of patients with stenosis <50%, and the second group of those with stenosis >50% (considered clinically significant). The criteria for >50% stenosis were PSV >125cm/s, with the additional criteria being ICA/CCA PSV ratio between 2 and 4 and ICA EDV >40cm/s, based on the Society of Radiologists in Ultrasound (SRU) consensus (25).

Pulsed spin-echo sequences (sagittal T1-weighted images, axial T2-weighted images), inversion recovery sequence FLAIR (*fluid attenuated inversion recovery*), especially sensitive to periventricular and peripheral brain lesions, and the gradient sequence T2*GRE for the detection of hemosiderin deposits, have been used in the brain MRI protocol. Changes in brain morphology and signal intensities concordant with previous lacunar, small, or large territorial brain infarcts were analyzed.

Anamnestic data on age, sex, height and weight, smoking, physical activity and existing hypertension, diabetes mellitus, hyperlipidemia, cardiovascular and cerebrovascular diseases, i.e. examinees' sociodemographic characteristics, functions and previous diseases and treatments relevant for cerebrovascular disease have also been gathered.

Statistical analysis

Variable intercorrelation has been done by point-biserial correlation coefficient for dichotomous variables, and by Phi coefficient for two dichotomous variables. The Fisher and Mann-Whitney U test were conducted for correlation of stenosis degree on CD-US for ACC, ACI and ACE bilaterally and the calcifications on OPGs on both sides. The correlation of age and weight with the stroke has been performed using the Welch t-test, and the correlation between the stroke and the other risk factors has been done using the Fisher test. The statistically significant level was set at p=0.05. The statistical analyses were performed using IBM SPSS Statistics 26 software.

Results

Forty-one subjects, among which twenty-eight women (68.3%) and thirteen men (31.7%) participated in the study, with the mean age of 66 years (range 52-80). All of them had calcifications in the projection of carotid arteries on OPGs, either unilaterally (N=20; 48.8%) or bilaterally (N=21; 51.2%).

Table 1 Number of calcifications in the projection of carotids detected on orthopantomographs, according to side.
Tablica 1. Broj kalcifikata u projekciji karotida na ortopantomogramima, ovisno o strani

mens Aera 1.5T iz 2018. godine. Nalaze su očitavali iskusni radiolozi.

Unutarnji i proksimalni dijelovi vanjskih karotidnih arterija obostrano su pregledani ultrazvukom s pomoću lineare visokofrekventne sonde. Obavljeni su pregledi ultrazvukom u sivoj skali, CD-UZV i spektralna analiza. Određene su brzine protoka i arterijski spektri u zajedničkoj karotidnoj arteriji (CCA), unutarnoj karotidnoj arteriji (ICA) i vanjskoj karotidnoj arteriji (ECA) obostrano te stupnjevi stenoze. Ispitanici su bili podijeljeni u dvije kategorije – prvu skupinu činili su pacijenti sa stenozom < 50 %, a drugu oni sa stenozom > 50 % (smatra se klinički značajnom). Kriteriji za > 50 % stenu bili su PSV > 25 cm/s, uz dodatne kriterije ICA/CCA PSV omjer između 2 i 4 i ICA EDV > 40 cm/s, na temelju konsenzusa Društva radiologa u ultrazvuku (SRU) (25).

U protokolu za MR mozga korištene su pulsne *spin-echo* sekvence (sagitalne T1-mjerene snimke, aksijalne T2-mjerene snimke), sekvenca FLAIR (*fluid attenuated inversion recovery*) posebno osjetljiva za periventrikularne i periferno smještene lezije mozga i gradijentna sekvenca T2*GRE za otkrivanje hemosiderinskih depozita. Analizale su se promjene u morfologiji i intenzitetu signala moždanoga parenhima koje radiomorfološki odgovaraju preboljelim lakinarnim, malim ili velikim teritorijalnim infarktima mozga.

Priključeni su i anamnestički podaci o dobi, spolu, tjelesnoj masi i visini, pušenju, tjelesnoj aktivnosti, postojećoj hipertenziji, šećernoj bolesti, hiperlipidemiji, kardiovaskularnim i cerebrovaskularnim bolestima, odnosno o sociodemografskim značajkama, funkcijama i navikama te prethodnim bolestima i liječenjima relevantnim za cerebrovaskularne bolesti.

Statistička analiza

Interkorelacija varijabli rađena je pointbiserijalnim koeficijentima korelaciјe za dihotomne varijable te Phi-koeficijentima asocijacije za dvije dihotomne varijable. Fisherov i Mann-Whitneyev U test korišteni su za određivanje korelaciјe stupnja stenoze na CD-UZV-u za ACC, ACI i ACE bilateralno i kalcifikacija na ortopantomogramima s obje strane. Korelacija dobi i tjelesne mase s moždanim udarom provedena je s pomoću Welchova t-testa, a korelacija moždanoga udara i ostalih čimbenika rizika Fisherovim testom. Statistički značajna razina postavljena je na p = 0,05. Za statističku analizu korišten je softver IBM-a SPSS Statistics 26.

Rezultati

U istraživanju je sudjelovao četrdeset i jedan ispitanik, od kojih dvadeset i osam žena (68,3 %) i trinaest muškaraca (31,7 %). Prosječna dob bila je 66 godina (raspon godina 52 – 80). Svi sudionici imali su kalcifikacije u projekciji karotidnih arterija na ortopantomogramima jednostrano

b Not possible to calculate the correlation because the variable is constant (it has only one value) • Nije moguće izračunati korelaciju jer je varijabla konstantna (ima samo jednu vrijednost)

Calcifications were seen on the right side in 32 patients (78%), and on the left side in 30 patients (73.2%) (Table 1). There was no statistically relevant correlation between the calcifications on either side and the risk factors for stroke, except for the hypertension and the calcifications on the left side ($p<0.05$). Negative correlation has been found between the calcifications on the left and on the right side ($p<0.05$) (Table 2).

Stenosis of >50% on CD-US was found in 6 patients (14.63%), overall in 12 arteries. All other patients had stenosis of <50% seen on CD-US (Table 3). No statistically relevant correlation between the significant stenosis on CD-US and the calcification on the OPG was found.

We have collected our subjects' sociodemographic and anamnestic data relevant to stroke risk. Hyperlipidemia was found in almost two-thirds (63.4%) of our examinees, hypertension was present in more than half (58.5%), diabetes in 12.2%, cardiovascular diseases were found in 26.8%, and cerebrovascular diseases in 29.3% of our patients. Nineteen (46.3%) patients were smokers, with another 12.2% being former smokers, and 33 (80.5%) were physically active (Table 4). Statistically significant intercorrelations were found between the male sex and weight ($p<0.01$), as well as with male sex and hypertension ($p<0.05$), between female

($N = 20$; 48.8 %) ili obostrano ($N = 21$; 51.2 %). Kalcifikacije su uočene desno kod 32 bolesnika (78 %), a lijevo kod njih 30 (73.2 %) (tablica 1.). Nije bilo statistički značajne korelacije između kalcifikacija na bilo kojoj strani i čimbenika rizika za moždani udar, osim za hipertenziju i kalcifikacije na lijevoj strani ($p < 0.05$). Utvrđena je negativna korelacija između kalcifikacija na lijevoj i desnoj strani ($p < 0.05$) (tablica 2.).

Stenoza >50 % na CD-UZV-u pronađena je kod 6 pacijenata (14,63 %), ukupno u 12 arterija. Svi ostali imali su stenuzu < 50 % na CD-UZV-u (tablica 3.). Nije pronađena statistički relevantna korelacija između signifikantne stenoze na CD-UZV-u i kalcifikacija na ortopantomogramima.

Prikupljeni su sociodemografski i anamnistički podaci ispitanika relevantni za rizik od moždanoga udara. Hipertlipidemiju je imalo gotovo dvije trećine (63,4 %) pacijenta, hipertenziju više od polovine (58,5 %), dijabetes 12,2 %, kardiovaskularne bolesti 26,8 %, a cerebrovaskularne bolesti njih 29,3 %. Devetnaest (46,3 %) ispitanika puši, još 12,2 % bivši su pušači, a 33 (80,5 %) tjelesno su aktivni (tablica 4.). Utvrđene su statistički značajne interkorelacije između muškoga spola i tjelesne težine ($p < 0,01$), muškog spola i hipertenzije ($p < 0,05$), ženskoga spola i hiperlipidemije ($p < 0,01$),

sex and hyperlipidemia ($p<0.01$), and also between the hypertension and weight ($p<0.05$) and hypertension and diabetes ($p<0.05$), and between the cardiovascular diseases and the age ($p<0.01$) and cardiovascular diseases and hyperlipidemia ($p<0.05$) (Table 2).

Six patients had signs of previous stroke on brain MRI (14.6%). Two patients had territorial infarcts and four patients had small cortical or lacunar infarcts in basal ganglia and brainstem. Their mean age was five years higher than of those without the previous stroke ($p<0.05$) (Table 5). There was a positive correlation with cerebrovascular diseases in these patients ($p<0.01$) (Table 6). No statistically significant difference in weight, hypertension, diabetes, hyperlipidemia, cardiovascular diseases, smoking or physical activities has been found between the examinees with or without stroke.

Discussion

The prevalence of calcifications with radiomorphologic characteristics suggestive of calcified atherosclerotic plaques on OPGs in our study was 8.07%. Previously reported prevalence in the general population has been 3-15% (4,8,12,15,16,26), which is in concordance with our finding.

We had a larger number of women with calcifications in the projection of carotid arteries in our study (68.3%) compared to men (31.7%). In their review article, Alves et al. confirm this finding (9), as well as Gonçalves et al. who also had a higher percentage of female patients with calcifications (26). In our study, the number of bilateral and unilateral calcifications was almost equal, with a slight advantage in favor of unilateral findings (51.2%) and with no strong predilection for right or left side. We also found a negative correlation between the calcifications on the left and the right side ($p<0.05$), which means that patients with a calcification on one side are less likely to have another calcification on the other side. These findings agree with those of Alves et al. who reported that calcifications are usually unilateral, but that there is no predilection for either side (9).

Our subjects' sociodemographic and anamnestic data relevant to stroke risk have been collected and correlated with the calcifications on OPGs. Hypertension, diabetes and smoking have shown positive correlations with calcifications, and physical activity showed negative correlation with calcifications, but the only statistically significant correlation was with hypertension ($p<0.05$), which was present in 58.5% of our examinees. Abecasis et al. had a hypertension prevalence of almost 62% in their study, and their results showed that patients with hypertension have more than 5 times greater probability to develop atheromatous plaques (27). A significant correlation between the number of years of smoking and carotid plaques has been mentioned by Abecasis et al. and Kumagai et al. in their previous studies (27,28), as well as the association of calcifications and diabetes by Friedlander et al. and Johansson et al. (11,24). Regular physical activity is a protective factor for vascular diseases (29), and activity is inversely associated with carotid plaque formation, especially in patients with increased vascular risk (30,31). However, the literature on correlation between calcified carotid plaques on

između hipertenzije i tjelesne težine ($p < 0,05$), hipertenzije i dijabetesa ($p < 0,05$), između kardiovaskularnih bolesti i dobi ($p < 0,01$) te kardiovaskularnih bolesti i hiperlipidemije ($p < 0,05$) (tablica 2.).

Šest pacijenata imalo je znakove preboljelog moždanoga udara na MR-u mozga (14,6%). Dva su imala teritorijalne infarkte, a četiri kortikalne ili lakunarne infarkte u bazalnim ganglijima i moždanome deblu. Prosječna dob tih ispitanika bila je pet godina viša od onih bez prethodnoga moždanoga udara ($p < 0,05$) (tablica 5.), uz pozitivnu korelaciju s cerebrovaskularnim bolestima ($p < 0,01$) (tablica 6.). Nije utvrđena statistički značajna razlika u tjelesnoj težini, hipertenziji, dijabetesu, hiperlipidemiji, kardiovaskularnim bolestima, pušenju ili tjelesnim aktivnostima između ispitanika s moždanim udarom i bez moždanoga udara.

Raspis

Prevalencija kalcifikacija radiomorfoloških karakteristika kalcificiranih aterosklerotskih plakova na ortopantomogramima u našem istraživanju bila je 8,07 %. U dosad objavljenim radovima autori navode prevalenciju u općoj populaciji od 3 do 15 % (4, 8, 12, 15, 16, 26), što je u skladu s našim nalazom.

U našem istraživanju bio je veći broj žena s kalcifikacijama u projekciji karotidnih arterija (68,3 %) u odnosu prema muškarcima (31,7 %). U svojem preglednom članku Alves i suradnici potvrđuju taj nalaz (9), kao i Gonçalves i suradnici koji su također imali veći postotak pacijentica s kalcifikacijama (26). Broj pacijenata s bilateralnim i unilateralnim kalcifikacijama bio je gotovo jednak u ovom istraživanju, s blagom prednosti u korist jednostranoga nalaza (51,2 %) i bez izražene predilekcije desne ili lijeve strane. Također je pronađena negativna korelacija između kalcifikacija na lijevoj i desnoj strani ($p < 0,05$), što znači da pacijenti s kalcifikacijama na jednoj strani imaju manju vjerojatnost kalcifikacija na drugoj strani. Ti se nalazi slažu s onima Alvesa i suradnika koji su izvjestili da su kalcifikacije obično jednostrane i bez sklonosti za jednu stranu (9).

Sociodemografski i anamnistički podatci ispitanika relevantni za rizik od moždanoga udara prikupljeni su i korelirani s kalcifikacijama na ortopantomogramima. Hipertenzija, šećerna bolest i pušenje pokazali su pozitivnu korelaciju s kalcifikacijama, a tjelesna aktivnost negativnu, no jedina statistički značajna korelacija bila je s povišenim krvnim tlakom ($p < 0,05$) od čega je patilo 58,5 % ispitanika. U studiji dr. Abecasis i suradnika prevalencija hipertenzije bila je gotovo 62 %, a njihovi rezultati pokazali su da pacijenti s hipertenzijom imaju više od 5 puta veću vjerojatnost za pojavu ateromatoznih plakova (27). Značajnu korelaciju između broja godina pušenja i karotidnih plakova naveli su u svojim studijama Abecasis i suradnici te Kumagai i suradnici (27, 28), a Friedlander i suradnici te Johansson i suradnici istaknuli su povezanost kalcifikacija i dijabetesa (11, 24). Redovita tjelesna aktivnost zaštitni je čimbenik za vaskularne bolesti (29) te je obrnuto proporcionalna stvaranju karotidnoga plaka, osobito ako je pacijent u povećanom vaskularnom riziku (30, 31). Ipak, ne-mnogo radova o korelaciji kalcificiranih karotidnih pla-

OPGs and physical activity seems to be scarce. The study of Helmi et al. showed a positive correlation between the plaque formation and irregular exercise, but with no statistical significance (32).

In this study, clinically significant stenosis of >50% on CD-US was found in 6 patients (14.63%), in 12 arteries respectively. Constantine et al. obtained similar results with 15.4% patients with calcifications having a carotid stenosis of over 50%, and showing a threefold higher risk of significant stenosis compared to those without calcifications (33). Several studies have shown higher percentage of significant carotid stenosis. Friedlander et al. have found >50% carotid stenosis on CD-US in 23% asymptomatic patients with calcified carotid plaques (15), and Almog et al. in 50% of sonographically examined arteries in their study (4). On the other hand, Johansson and al. found a significant stenosis in only 7% of the patients with positive OPG calcifications (24). Studies that performed the OPGs after the significant carotid stenosis had already been proven and before the carotid endarterectomy was been carried out showed high percentages of visible calcifications on OPGs. Giantsos et al. had positive calcification findings on 70% orthopantomographs of such patients (22) and Garoff et al. in 84% of examinees (23).

Our study showed no statistically relevant correlation between the significant stenosis on CD-US and the calcifications on the OPG. These results are coherent with the study of Johansson et al. (24) and Constantine et al. (33), but in disagreement with the results of Almog et al. (4) and Abecais et al. (27). For instance, the latter study found fifteen times greater risk of stenosis >70% on CD-US in the group of patients with calcified plaques (27).

The connection between stroke and calcified carotid artery calcifications seen on OPGs has been discussed by several authors (12,22,27,33,35-37). In a retrospective study, Cohen et al. have shown that 34% of the patients with calcifications in the projection of carotids on orthopantomographs have subsequently developed a myocardial infarction or stroke in the period of 3.5 years (12). Freidlander et al. have claimed that individuals with calcified carotid atheromas have a higher risk of experiencing similar major vascular events in the future (37). In our sample, nearly 15% of patients have had a stroke. Cerebrovascular disease and older age are known risk factors for stroke (3,34), which was confirmed by our results. There was a significant correlation ($p<0.01$) between existing cerebrovascular disease and stroke, and our patients with stroke were approximately 5 years older than those with no previous stroke ($p<0.05$).

The study findings are preliminary, based on the first 41 patients participating in a larger, ongoing study. More comprehensive evaluation with a larger sample is needed to investigate the significance of calcified carotid plaques on OPGs for detection of carotid artery stenosis in general population, and to determine their correlation with stroke.

kova na ortopantomogramima i tjelesne aktivnosti. Studija Helmija i suradnika pokazala je pozitivnu korelaciju između stvaranja plaka i neredovite tjelovježbe, no bez statističke značajnosti (32).

U ovom istraživanju klinički je značajna stenoza od > 50 % na CD-UZV-u pronađena kod 6 pacijenata (14,63 %), odnosno u 12 arterija. Constantine i suradnici dobili su slične rezultate, s 15,4 % pacijenata s kalcifikacijama koji su imali karotidnu stenuznu veću od 50 % i pokazivali trostruko veći rizik za signifikantnu stenuzu u usporedbi s onima bez kalcifikacija (33). Nekoliko istraživača objavilo je više postotke pacijenata sa značajnom karotidnom stenozom u svojim uzorcima. Friedlander i suradnici imali su karotidne steneze >50 % na CD-UZV-u za 23 % asimptomatskih pacijenata s kalcificiranim karotidnim plakovima (15), a Almog i suradnici u 50 % sonografski pregledanih arterija (4). S druge strane, Johansson i suradnici pronašli su značajnu stenuzu samo kod 7 % pacijenata s pozitivnim kalcifikacijama na ortopantomogramu (24). U studijama u kojima su se ortopantomogrami snimali ako je pacijentu bila dokazana značajna karotidna stenoza i prije karotidne endarterektomije, postotci vidljivih kalcifikacija na ortopantomogramima bili su visoki. Giantsos i suradnici imali su pozitivne nalaze kalcifikacija na 70 % ortopantomograma (22), a Garoff i suradnici kod 84 % ispitanika (23).

Naše istraživanje nije pokazalo statistički značajnu korelaciju signifikantne steneze na CD-UZV-u i kalcifikacija na ortopantomogramima. Ti su rezultati koherentni sa studijom Johansson i suradnika (24) i Constantinea i suradnika (33), no u suprotnosti su s rezultatima Almoga i suradnika (4) i Abecais i suradnika (26). Primjerice, u posljednjoj spomenutoj studiji istaknut je petnaest puta veći rizik za karotidnu stenuzu >70 % na CD-UZV-u u skupini pacijenata s kalcificiranim plakovima (27).

O povezanosti moždanoga udara i kalcifikacija karotidnih arterija vidljivih na ortopantomogramima raspravljaljalo je više autora (12, 22, 27, 33, 35 – 37). U retrospektivnoj studiji su Cohen i suradnici pokazali da je 34 % pacijenata s kalcifikacijama u projekciji karotidnih arterija na ortopantomogramima razvilo infarkt miokarda ili moždani udar u razdoblju od 3,5 godine nakon snimanja (12). Freidlander i suradnici navode da osobe s kalcificiranim karotidnim ateromima imaju u budućnosti veći rizik od ozbiljnijih vaskularnih dogadaja (37). U našem uzorku gotovo 15 % pacijenata imalo je moždani udar. Cerebrovaskularna bolest i starija dob poznati su čimbenici rizika za moždani udar (3, 34), što potvrđuju i naši rezultati. Postojala je značajna korelacija ($p < 0,01$) između postojeće cerebrovaskularne bolesti i moždanoga udara, a ispitanici s moždanim udarom bili su prosječno 5 godina stariji od onih bez prethodnoga moždanoga udara ($p < 0,05$).

Rezultati istraživanja su preliminarni, dobiveni su od prvih ispitanika – od četrdeset i jednoga iz veće studije koja je u tijeku. Potrebna je sveobuhvatnija analiza s većim uzorkom da bi se detaljnije istražilo značenje kalcificiranih karotidnih plakova na ortopantomogramima za otkrivanje steneze karotidne arterije u općoj populaciji i njihova korelacija s moždanim udarom.

Conclusion

Our study aimed to determine a correlation between the calcifications in the projection of carotids on OPGs and the carotid stenosis on CD-US and to analyze the relationship between stroke risk factors, calcifications in the projection of carotids on OPGs and the degree of carotid stenosis. Significant stenosis of over 50% was found in almost 15% of our patients, but no statistically significant correlation between calcifications on OPGs and significant stenosis on CD-US was found. Therefore, our hypothesis has not been confirmed by our preliminary results. Positive correlations with calcifications were shown for hypertension, diabetes and smoking, and negative correlation for physical activity, although the only statistically significant correlation was with hypertension. Nearly 15% of our examinees have had a stroke, and they were approximately 5 years older than those with no previous stroke. Further investigation and a larger sample is needed to determine the importance of calcifications in the projection of carotids on OPGs and their relationship with the significant stenosis and stroke.

Sažetak

Uvod: Ortantomografija jedna je od najčešće korištenih slikevnih metoda u dentalnoj medicini. Kalcifikacije u projekciji karotidnih arterija na ortantomogramima nalaze se kod 3 do 15 % opće populacije i diferencijalno dijagnostički su kalcificirani aterosklerotski plakovi. Aterosklerotske promjene karotidnih arterija među najčešćim su uzrocima moždanoga udara pa je ta bolest diljem svijeta drugi najčešći uzrok smrti i vodeći uzrok invalidnosti. Cilj ovoga rada bio je utvrditi odnos između kalcifikacija u projekciji karotidnih arterija na ortantomogramima, zatim između karotidne stenoze i moždanoga udara te korelaciju između čimbenika rizika za moždani udar, kalcifikacija na ortantomogramima i stupnja karotidne stenoze. **Materijal i metode:** Dopplerski ultrazvuk karotidnih arterija i MR mozga učinjeni su četrdeset i jednom pacijentu s jednostranim ili obostranim kalcifikacijama na ortantomogramima. Priključeni su anamnastički podaci o rizičnim čimbenicima za moždani udar. **Rezultati:** Signifikantna stenoza > 50 % nadena je kod gotovo 15 % pacijenata. Uočena je značajna korelacija između hipertenzije i karotidnih kalcifikacija. Između kalcifikacija i signifikante stenoze nije pronađena statistički značajna korelacija. Pacijenti s prethodnim moždanim udarom bili su prosječno 5 godina stariji od onih koji nisu doživjeli taj moždanožilni incident. **Zaključak:** Preliminarni rezultati nisu pokazali statistički značajnu korelaciju između kalcifikacija na ortantomogramima i signifikantne stenoze karotidnih arterija, no potrebna su daljnja istraživanja.

Zaključak

Cilj našeg istraživanja bio je odrediti povezanost kalcifikacija u projekciji karotidnih arterija na ortantomogramima i karotidne stenoze na CD-UZV-u te analizirati odnos između čimbenika rizika za moždani udar, kalcifikata u projekciji karotidnih arterija na ortantomogramima i stupnja karotidne stenoze. Signifikantna stenoza veća od 50 % pronađena je kod gotovo 15 % ispitanika, no statistički značajna korelacija kalcifikacija na ortantomogramima i signifikantne stenoze na CD-UZV-u nije pronađena. Naši preliminarni rezultati nisu potvrdili hipotezu. Pozitivna korelacija s kalcifikacijama postojala je za hipertenziju, dijabetes i pušenje, a negativna za tjelesnu aktivnost, iako je jedina statistički značajna korelacija bila s hipertenzijom. Gotovo 15 % naših ispitanika imalo je moždani udar, a bili su prosječno 5 godina stariji od onih koji ga nisu imali. Potrebno je daljnje istraživanje i veći uzorak da bi se utvrdila važnost kalcifikacija u projekciji karotidnih arterija na ortantomogramima i njihov odnos sa signifikantnom stenozom karotidne arterije i moždanim udarom.
