Abstract

Magnetic γ-Fe₂O₃@SiO₂ core-shell nanocomposite was prepared using Stöber method and functionalized firstly by isopropenyloxytrimethylsilane as a coupling agent to enter active acetylacetone on the surface of nanoparticles, and after that by the synthesized azo dye ligand, 2-(2-benzothiazolyl azo)-4-methoxyaniline. In such a way, γ-Fe₂O₃@SiO₂-azo dye hybrid nanocomposite was formed. The structure of the synthesized azo dye was evidenced by physical and chemical analysis using melting point, Fourier-transform infrared spectroscopy (FT-IR), CHNS elemental analysis, proton nuclear magnetic resonance (HNMR) and gas chromatography mass spectrometry (GC-MS). The magnetic properties, structure, element composition and morphology characterization of prepared materials (γ-Fe₂O₃, γ-Fe₂O₃@SiO₂ and γ-Fe₂O₃@SiO₂-azo dye) were investigated by vibrating sample magnetometer (VSM), X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), transmission electron spectroscopy (TEM) and field electron scanning electron microscopy-energy dispersive X-ray-mapping techniques. The electrochemical performance of synthesized γ-Fe₂O₃, γ-Fe₂O₃@SiO₂ and γ-Fe₂O₃@SiO₂-2-(2-benzothiazolyl azo)-4-methoxyaniline electrodes were carried out using cyclic voltammetry (CV), galvanostatic charge-discharge (GCD) and electrochemical impedance spectroscopy (EIS). It was shown that the finally prepared γ-Fe₂O₃@SiO₂-2-(2-benzothiazolyl azo)-4-methoxyaniline) hybrid nanocomposite electrode possesses good storage charge capability of 580 F g⁻¹ at 1 A g⁻¹.

Keywords

Hybrid nanocomposite; maghemite nanoparticles; azo dye ligand; supercapacitor electrode; coatings

Introduction

Supercapacitor (SC) is a storage energy device with long cycle life, high power density and fast recharge capability, but in spite of many advantages, SCs still suffer from the low density of energy
before they could have authentic electric applications [1,2]. SC is composed of two electrodes (anode and cathode), membrane and electrolyte solution. Different metal oxides, sulfides [3], hydroxides [4], and metal complexes [5] have already been studied as electrode materials to improve the capacitance of SC. In order to attain high efficiency, two electrodes should store the energy or charges equally, which means that if one electrode stores charge more than the other, it will cause a difference in the charge balance of the electrodes of SC [6].

Maghemite phase ($\gamma$-Fe$_2$O$_3$) is one of the auspicious electrode materials because of its natural abundance and large specific capacitance [7,8]. The electrochemical behavior of iron oxide [9] and iron oxide coated by SiO$_2$ have already been examined, but without reporting their supercapacitance or electrochemical performance [10-12]. However, their chemical stability, good theoretical capacitance and low cost have resulted in protracted studies targeted to improve the electrochemical properties of iron oxides. The studies reported that as high as 207 F g$^{-1}$ specific capacitance for iron oxide prepared from ultrasonic method [13]. We believe that incorporating of $\gamma$-Fe$_2$O$_3$ with ligand compounds nanocomposite may be an effective method to enhance electrochemical properties and performance [14,15]. So, the maghemite/ligand hybrid nanocomposite will be more committing electrode for supercapacitor than pure maghemite. In this paper, we report the synthesis of azo dye on the surface of silica-coated magnetic maghemite nanoparticles incorporated with 2-(2-benzothiazolylazo)-4-methoxyaniline ligand as new nanomagnetic electrodes for supercapacitor applications.

**Experimental**

**Materials**

In this work, the reagents and solvent were purchased from Fisher Scientific and Sigma-Aldrich with 98 % purity, while other chemical materials were supplied from Fluka. All chemicals were used without purification.

**Preparation of azo dye ligand**

A mixture (10 ml ethanol, 2 ml conc. HCl) has been used to melt of (0.335 g, 1 mM) of 2-amino-benzothiazole, and diazotized with 10 % solution of NaNO$_2$ at 5 °C. The mixture was added gradually with stirring to cool ethanolic solution (0.307 g, 1 mM) of 4-methoxyaniline. After that, 25 ml of 1 M NaOH solution was added to the colored mix and azo ligand was precipitate, filtrated and washed various times with (1:1) C$_2$H$_5$OH: H$_2$O, and left to dry. The reaction is shown in Scheme 1. Some other physical characteristics of the synthesized azo-dye are summarized as follows.

Color: deep brown. M.P. = 300 °C >. $^1$H NMR (400 MHz, DMSO-d$_6$): $\delta$ = 7.00-7.857 (m, 6H), 7.908 (s, 2H) (NH$_2$), 3.426 (s, 3H) (OCH$_3$). IR (cm$^{-1}$): $\nu$ (N-H) = 3387-3441, $\nu$ (C=N) = 1604, $\nu$ (C=C) = 1504, $\nu$ (N=N) = 1535 and 1568, $\delta$sss CH$_3$ = 1404 and 1387, 1309. $\lambda$$_{max}$ = 240, 354 and 412 nm. Elemental analysis calculated: C 58.92 %, H 3.92 %, N 18.98 %, O 4.98 %, S 10.92 %.

**Preparation of magnetic $\gamma$-Fe$_2$O$_3$ nanoparticles**

Potassium ferric oxalate K$_3$[Fe(C$_2$O$_4$)$_3$]·3H$_2$O was used as a source for synthesis of $\gamma$-Fe$_2$O$_3$ nanoparticles by photolysis method [16-18]. In a 125 W irradiation system, 1 g of ferric complex solution was irradiated for 30 min until a yellow precipitate of ferrous oxalate was formed. The precipitate was decanted, washed with distilled water and dried at 80 °C for 4 h. The dried precipitate was burned at 400 °C for 2 h.
Preparation of γ-Fe₂O₃@SiO₂@IPTMS

The preparation of γ-Fe₂O₃@SiO₂@IPTMS consists of two steps:

The first step consists of dispersing 0.5 g of the brown magnetic precipitate of γ-Fe₂O₃ in the mixture of water and 2-propanol with a ratio of 1:10 with stirring for 2 h at 22 °C. The mixture of oleic acid (10 ml), ammonium solution (28 %, 5 ml), distilled water (10 ml) and 5 ml of tetraethyl orthosilicate (TEOS) was added to the dispersing mixture under continuous stirring. The product was magnetically isolated and dried at 80 °C for 2 h, and used in the next step. The second step was carried out by dispersing 1 g of γ-Fe₂O₃@SiO₂ in 50 ml of 70 % ethanol solution by sonication process for 1 h. Then 2 ml of (3-iodopropyl)trimethoxysilane (IPTMS) was added to the mixture under a continuous stirrer. Finally, the product was magnetically isolated and dried at 80 °C for 2 h.

Preparation of γ-Fe₂O₃@SiO₂-2-(2-benzothiazolyl azo)-4-methoxyaniline

Firstly, (0.1 g) γ-Fe₂O₃@SiO₂@acetylacetone (synthesized from refluxed γ-Fe₂O₃@SiO₂@IPTMS with pentane-2,4-dione in the presence of sodium hydride) was dispersed in 10 ml mixture of water and ethanol with ratio (1:1) for 30 min. Then, 0.2 g of 2-(2-benzothiazolyl azo)-4-methoxyaniline was added to the dispersion mixture and refluxed for 10 h. After that, the functionalized magnetic nano-composite was separated by pieces of magnetic bar. Finally, it was washed several times with acetone and distilled water and dried at 80 °C for 3 h. All processes and prepared compounds are summarized in Scheme 2.

Electrochemical measurements

The electrochemical cell contained three electrodes, i.e., 1×1 cm pieces of prepared samples as working electrodes, Ag/AgCl (saturated KCl) as the reference electrode and Pt foil as the counter electrode. 1 M Na₂SO₄ was utilized as the electrolyte solution. The active material(s) (85 %), carbon black (10 %) and polyvinyl fluoride (5 %) were mixed by using a few drops of N-methyl-2-pyrrolidione solvent to obtain mixtures that were coated on the foil of graphite substrate (1 cm²) and dried in an oven for 10 h at 70 °C. The mass of active materials (γ-Fe₂O₃, γ-Fe₂O₃@SiO₂, and γ-Fe₂O₃@SiO₂- azo dye) on each of thus formed working electrodes was approximately 0.5 g. The three electrodes were utilized to examine the pseudocapacitive performance of prepared samples in terms of cyclic voltammetry (CV), galvanostatic charge-discharge (GCD) and electrochemical impedance spectroscopy.
Results and discussion

Azo ligand characterization

The 2-(2-benzothiazolyl azo)-4-methoxyaniline azo ligand was characterized using fragmentation electron effect. The results of hit mass spectroscopy (Figure 1) illustrated that the molecular weight of the C_{14}H_{12}N_{4}O_{5}S ligand is 284 g mol^{-1}. Peak at m/z = 284 is assigned to [M]+ and correlated with the prepared azo ligand. Set of peaks located at 210, 134, 77.2 and 35 are related to other fragmentation. The main fraction supported with cracking product is shown in Scheme 3.
Magnetic properties

The magnetic properties of prepared materials were investigated by vibrating sample magnetometry (VSM). The magnetization plots of γ-Fe₂O₃, γ-Fe₂O₃@SiO₂ and γ-Fe₂O₃@SiO₂-2-(2-benzothiazolyl azo)-4-methoxyaniline are shown in Figure 2. The results show that the saturation magnetization is equal to 25-40 emu g⁻¹ without any hysteresis loop. In addition, the results show quick ascension in magnetization curves without any coercivity and the samples show supermagnetic behavior at room temperature. These magnetic properties of prepared nanoparticles are pivotal in their applications since they prevent aggregation of particles and enable their re-dispersion in the reaction medium in the absence of a magnetic field [19].
Structure characterization

The structure properties of $\gamma$-Fe$_2$O$_3$, $\gamma$-Fe$_2$O$_3$@SiO$_2$ and $\gamma$-Fe$_2$O$_3$@SiO$_2$-2-(2-benzothiazolyl azo)-4-methoxyaniline were evaluated by XRD and XPS. The XRD of $\gamma$-Fe$_2$O$_3$, $\gamma$-Fe$_2$O$_3$@SiO$_2$, azo ligand 2-(2-benzothiazolyl azo)-4-methoxyaniline, and $\gamma$-Fe$_2$O$_3$@SiO$_2$-2-(2-benzothiazolyl azo)-4-methoxyaniline are presented in Figure 3A-D, respectively. The results in Figure 3A show diffraction peaks located at 30.1, 35.6, 43.2, 53.4, 57.1 and 62.5°, which correspond to face-centered cubic (220), (311), (400), (422), (511) and (440) crystalline planes, in agreement with (JCPDS-39-1340). On the other side, the results (Figure 3B) show a new diffraction peak centered at 22.8°, which corresponds to (110) plane of amorphous SiO$_2$. By comparing diffraction peaks of $\gamma$-Fe$_2$O$_3$ and $\gamma$-Fe$_2$O$_3$@SiO$_2$, it was found that the coated SiO$_2$ doesn’t change the structure of $\gamma$-Fe$_2$O$_3$. As can be seen (Figure 3D), the presence of sharp peaks confirms that the structure of $\gamma$-Fe$_2$O$_3$@SiO$_2$ remains crystalline after being coated with a layer of azo ligand [20,21].

![Figure 3. XRD patterns of: (A) $\gamma$-Fe$_2$O$_3$, (B) $\gamma$-Fe$_2$O$_3$@SiO$_2$, (C) azo ligand, and (D) $\gamma$-Fe$_2$O$_3$@SiO$_2$-azo ligand](image)

The chemical composition of $\gamma$-Fe$_2$O$_3$, $\gamma$-Fe$_2$O$_3$@SiO$_2$ and $\gamma$-Fe$_2$O$_3$@SiO$_2$-2-(2-benzothiazolyl azo)-4-methoxyaniline was characterized using XPS. The XPS of prepared compounds corresponding to C, N, O, Si, S and Fe energy levels are presented in Figures 4A to 4F. The energy level of C (Figure 4A) shows three peaks located at 283.5, 286.2 and 289.1 eV corresponding to C-C, C=N and C=C bonds, respectively, which confirm bonding of acetylacetone and N of 2-(2-benzothiazolyl azo)-4-methoxyaniline ligand [22,23]. The spectrum energy level of N 1s is illustrated at Figure 4B. The spectrum can be deconvoluted to 398.4, 399.5 and 401.2 eV, corresponding to [-C=N-], [-N=N-] and [-NH-], respectively [24]. At 531.8 eV, the energy level spectrum is shown (Figure 4C), which is related to O 1s, confirming the presence of O$^2-$ in the composite [25]. As shown in Figure 4D, the characteristic peak of Si 2p is clearly formed at 103.2 eV, which indicates the successful coating of SiO$_2$ around $\gamma$-Fe$_2$O$_3$. 

![Figure](image)
Figure 4. XPS of: (A) C 1s, (B) N 1s, (C) O 1s, (D) Si 2p, (E) S 2p, (F) Fe 2p, $\gamma$-Fe$_2$O$_3$@SiO$_2$-azo dye and (G) survey spectra of $\gamma$-Fe$_2$O$_3$@SiO$_2$ and $\gamma$-Fe$_2$O$_3$@SiO$_2$-2-(2-benzothiazolyl azo)-4-methoxyaniline
When comparing the survey spectrum of $\gamma$-Fe$_2$O$_3$@SiO$_2$ and $\gamma$-Fe$_2$O$_3$@SiO$_2$-2-(2-benzothiazolyl azo)-4-methoxyaniline (Figure 4e), a new peak centered at 145.67 eV is found, corresponding to level energy spectrum of S 2p. This indicates the successfully incorporated ligand with $\gamma$-Fe$_2$O$_3$@SiO$_2$. On the other side, the survey spectrum of prepared compounds shows a small peak of Fe, which approves the coating of Fe$_3$O$_4$ by SiO$_2$.

**Morphology characterization**

The morphology of $\gamma$-Fe$_2$O$_3$, $\gamma$-Fe$_2$O$_3$@SiO$_2$ and $\gamma$-Fe$_2$O$_3$@SiO$_2$-2-(2-benzothiazolyl azo)-4-methoxyaniline were performed utilizing TEM, FESEM and EDX-mapping. TEM images of prepared compounds are shown in Figures 5A to 5C.

**Figure 5.** TEM images of (A) $\gamma$-Fe$_2$O$_3$, (B) $\gamma$-Fe$_2$O$_3$@SiO$_2$, (C) $\gamma$-Fe$_2$O$_3$@SiO$_2$-azo ligand; FESEM images of (D) $\gamma$-Fe$_2$O$_3$, (E) $\gamma$-Fe$_2$O$_3$@SiO$_2$, (F) $\gamma$-Fe$_2$O$_3$@SiO$_2$-azo ligand, and SAED images of: (g) $\gamma$-Fe$_2$O$_3$, (h) $\gamma$-Fe$_2$O$_3$@SiO$_2$-azo ligand
The results (Figure 5A) clearly display agglomerates of spherical \( \gamma \)-Fe\(_2\)O\(_3\) nanoparticles with 11 nm grain size. TEM images illustrate the core-shell system structure of \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\) and confirm the perfect coating of \( \gamma \)-Fe\(_2\)O\(_3\) nanoparticles by SiO\(_2\), as shown in Figure 5B. On the other side, the results (Figure 5C) illustrate the complete surrounding of 2-(2-benzothiazolyl azo)-4-methoxyaniline layer around \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\), which indicates success in the preparation of the final compound. The microscope evaluation of \( \gamma \)-Fe\(_2\)O\(_3\), \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\) and \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(2-benzothiazolyl azo)-4-methoxyaniline were investigated using FESEM. The FESEM images of prepared compounds are shown in Figure 5d-f. The results (Figure 5D) show that the magnetic \( \gamma \)-Fe\(_2\)O\(_3\) particles were formed in uniform shapes with apparent agglomeration due to their magnetic properties. Added SiO\(_2\) to magnetic \( \gamma \)-Fe\(_2\)O\(_3\) makes the shapes of catalyst nanoparticles spherical (Figure 5e). The FESEM images of \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(2-benzothiazolyl azo)-4-methoxyaniline show nanocomposite with a small agglomeration of particles, which may be back to fictionalized of \( \gamma \)-Fe\(_2\)O\(_3\) by 2-(2-benzothiazolyl azo)-4-methoxyaniline layer. The results of FESEM are in agreement with XRD and TEM results. The lattice fingers of \( \gamma \)-Fe\(_2\)O\(_3\) and \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(2-benzothiazolyl azo)-4-methoxyaniline are shown in Figure 5g-h. The results show the highly crystalline nature of \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\)-azo, as well as the well-organized dots and ring (Figure 5h), prove the crystalline nature of synthesized material that could be beneficial in structure retention for long-term stability. On the other side, a large number of gleam spots (Figure 5h) compared with pure \( \gamma \)-Fe\(_2\)O\(_3\) (Figure 6g) elucidates the coating of \( \gamma \)-Fe\(_2\)O\(_3\) by SiO\(_2\) [27,28].

The chemical composition of \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(2-benzothiazolyl azo)-4-methoxyaniline was investigated by element mapping patterns, while compositions of \( \gamma \)-Fe\(_2\)O\(_3\) and \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\) were carried out by EDX analysis. The EDS spectrum result (Figure 6) of \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(2-benzothiazolyl azo)-4-methoxyaniline shows detectable singles back to Fe, O, Si, S, N and S, as well as the weight percentage of detecting elements, suggesting that the nanocomposite was successfully prepared.

![Figure 6. EDS spectrum of \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(2-benzothiazolyl azo)-4-methoxyaniline and mapping of Fe, Si, S, N, O, C](Image)

The EDX spectra of \( \gamma \)-Fe\(_2\)O\(_3\) and \( \gamma \)-Fe\(_2\)O\(_3\)@SiO\(_2\) are shown in Figure 7. Clear peaks related to Fe and O without other peaks are evident in Figure 7A, which indicates the successful preparation of pure ferric oxide. A new peak related to Si can be detected from EDX analysis after the coating of Fe\(_2\)O\(_3\) by SiO\(_2\) (Figure 7B).

http://dx.doi.org/10.5599/jese.1657
Vs of prepared compounds were recorded at different scan rates and within 0.1-2 V potential window, as presented in Figure 8. The CVs of \( \gamma\)-Fe\(_2\)O\(_3\), \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\) and \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline examined at 10 mV s\(^{-1}\) are shown in Figure 8A. The results demonstrate redox peaks for \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline, and higher specific capacitance was observed. The CVs of \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline at different scan rates are presented in Figure 8B. The results show redox peaks until the highest scan rates with slight shifting, which indicates good electrode capability. On the other hand, the separation of current peaks raised with the rising scan rate because the redox peaks change with reversible reactions between the electrode and electrolyte solution [31]. The specific capacitance \( C_p \) of prepared electrodes was evaluated by using equation 1) [32]:

**BET analysis**

The specific area, mean size of particles and the volume of pores for \( \gamma\)-Fe\(_2\)O\(_3\) and \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline were investigated using BET analysis, and the results are summarized in Table 1. The results show that the surface area of \( \gamma\)-Fe\(_2\)O\(_3\) and \( \gamma\)-Fe\(_2\)O\(_3\) functionalized by SiO\(_2\) and azo compound was 99.3 and 275.5 m\(^2\)/g, respectively, meaning that the functionalized compound has higher surface area due to the presence of silica and azo dye and so, higher capacity for adsorption of species on the electrode surface. In addition, the results demonstrated that the mean pore size of \( \gamma\)-Fe\(_2\)O\(_3\) and \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline are 3.9 and 4.3 nm, respectively. According to the IUPAC categories, both prepared electrode materials can be classified into mesopores group [29,30].

**Electrochemical performance**

The electrochemical properties of \( \gamma\)-Fe\(_2\)O\(_3\), \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\) and \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline electrodes were investigated using CV, GCD and EIS techniques. The specific capacitances of three electrodes in the presence 1 M Na\(_2\)SO\(_4\) as electrolyte solution were calculated using cyclic voltammetry data. The CVs of prepared compounds were recorded at different scan rates and within 0.1-2 V potential window, as presented in Figure 8. The CVs of \( \gamma\)-Fe\(_2\)O\(_3\), \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\) and \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline examined at 10 mV s\(^{-1}\) are shown in Figure 8A. The results demonstrate redox peaks for \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline electrode. In addition, the CV result of \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\) showed significant improvement when its surface was modified with 2-(benzo thiazolyl azo)-4-methoxyaniline, and higher specific capacitance was observed. The CVs of \( \gamma\)-Fe\(_2\)O\(_3\)@SiO\(_2\)-2-(benzo thiazolyl azo)-4-methoxyaniline at different scan rates are presented in Figure 8B. The results show redox peaks until the highest scan rates with slight shifting, which indicates good electrode capability. On the other hand, the separation of current peaks raised with the rising scan rate because the redox peaks change with reversible reactions between the electrode and electrolyte solution [31]. The specific capacitance \( C_p \) of prepared electrodes was evaluated by using equation 1) [32]:

![EDX spectra of: (A) γ-Fe2O3 and (B) γ-Fe2O3@SiO2](image-url)
where \( A \) is the area under plot, \( \nu / \text{V s}^{-1} \) scan rate, \( m / g \) is the active mass of the electrode, and \( \Delta V \) is a potential window. The results are shown in Figure 8C. The results exhibit that the modified \( \gamma \)-Fe\(_2\)O\(_3@\)SiO\(_2\) by azo ligand (2-(2-benzothiazolyl azo)-4-methoxaniline) has higher specific capacitance than \( \gamma \)-Fe\(_2\)O\(_3@\)SiO\(_2\) and \( \gamma \)-Fe\(_2\)O\(_3\), because of the interaction between the ferric oxide and azo ligand, which makes the structure of electrode superior and easy for Na\(_2\)SO\(_4\) electrolyte solution accessibility.

The specific capacitance of prepared electrodes was also examined at different scan rates 10-100 mV s\(^{-1}\) and the results are also presented in Figure 8C. The results show a reduction in specific capacitance values with increasing scan rate because of difficult redox transition at high scan rate value [33,34].

The GCD measurements of prepared compounds (\( \gamma \)-Fe\(_2\)O\(_3\), \( \gamma \)-Fe\(_2\)O\(_3@\)SiO\(_2\) and \( \gamma \)-Fe\(_2\)O\(_3@\)SiO\(_2\)-azo ligand electrodes) were performed at different current densities (0-10 mA g\(^{-1}\)) in the presence of 1 M Na\(_2\)SO\(_4\) as the electrolyte solution. The results show that discharge times are decreased with increasing current density due to increased drop voltage. At different current densities, the specific capacitance value was calculated using the following equation [35]:

\[
C_{sp} = \frac{A}{2\nu m \Delta V}
\]

\((1)\)

\[
\Delta C = \Delta V \times \text{It}
\]

\((2)\)
where \( I \) is the current density in the GCD experiment, \( \Delta t \) is discharge time, \( m \) is the mass of active material (0.5 g) and \( \Delta V \) is the potential window. The specific capacitance values of prepared compounds at different current densities are summarized in Table 2.

Table 2. Specific capacitance values obtained by GCD measurements at different current densities

<table>

The results show that specific capacitance is promoted by incorporating 2-(2-benzothiazolyl azo)-4-methoxyaniline with \( \gamma\text{-Fe}_2\text{O}_3\text{-SiO}_2 \) compared with \( \gamma\text{-Fe}_2\text{O}_3 \) electrode because of providing more active sites for transferring electrons inside the electrodes and many sites for storing energy. On the other hand, the results show a decrease in the specific capacitance with increasing current density because there is not enough time for ions to arrive at the surface of the electrode and work in electrochemical reactions \[36-39\].

The cycling stabilities of \( \gamma\text{-Fe}_2\text{O}_3@\text{SiO}_2\text{-2-(2-benzothiazolyl azo)-4-methoxyaniline} \) and \( \gamma\text{-Fe}_2\text{O}_3 \) electrodes are investigated by GCD measurements (Figure 9) at 10 A/g current density for 1000 cycles. Pure \( \gamma\text{-Fe}_2\text{O}_3 \) electrode shows lower stability compared with the functionalized electrode due to its destruction \textit{via} large current, discharge and circular charge \[39\]. After 750 cycles at 10 A g\(^{-1}\), the functionalized electrode exhibited higher stability compared with \( \gamma\text{-Fe}_2\text{O}_3 \), with 92 % of initial capacitance remaining after 1000 cycles, which indicates a good role of the azo compound in the cycle stability of the electrode.

Figure 9. Cycling stability of \( \gamma\text{-Fe}_2\text{O}_3 \) and \( \gamma\text{-Fe}_2\text{O}_3@\text{SiO}_2\text{-azo ligand electrodes} \)

From electrochemical measurements, our prepared hybrid nanocomposite shows a very good capability to store the charges and electric energy (580 F g\(^{-1}\)) when comparing it with other polymeric and binary oxide compounds (Table 3). It can be noted that the synthesized \( \gamma\text{-Fe}_2\text{O}_3@\text{SiO}_2\text{-2-(2-}
-benzothiazolyl azo)-4-methoxyaniline) hybrid nanocomposite has interesting electrochemical properties already reported in the literature.

Table 3. Specific capacitance for some iron oxide composites (current density = 1 A g⁻¹)

Conclusion

Stöber method was used to prepare γ-Fe₂O₃@SiO₂ core-shell nanocomposite that was functionalized by 2-(2-benzothiazolyl azo)-4-methoxyaniline modified-MNPS, and characterized by different techniques such as XRD, XPS, TEM, FESEM-EDX-mapping, while the electrochemical performance CV, GCD and EIS. Electrochemical characterization showed good cycling stability, good rate capability and high specific capacitance of 580 F g⁻¹ at 1 A g⁻¹ current density. After 100 cycles, the specific capacitance of γ-Fe₂O₃@SiO₂-azo ligand electrodes is reduced to 92 % of retention capacitance. The good electrochemical performance and simple and easy fabrication of γ-Fe₂O₃@SiO₂-azo suggest that this material is a promising capacitor electrode.

Conflicts of Interest: The authors declare no conflict of interest.
